

Bluetooth® low energy wireless system-on-chip

Datasheet - production data

Features

- Bluetooth low energy single mode system-on-chip compliant with its specifications:
 - master, slave and multiple simultaneous roles
- Operating supply voltage: from 1.7 to 3.6 V
- Integrated linear regulator and DC-DC step-down converter
- Operating temperature range: -40 °C to 105 °C
- High performance, ultra-low power Cortex-M0 32-bit based architecture core
- Programmable 160 kB Flash
- 24 kB RAM with retention (two 12 kB banks)
- 1 x UART interface
- 1 x SPI interface
- 2 x I²C interface
- 14 or 15 GPIO
- 2 x multifunction timer
- 10-bit ADC
- Watchdog and RTC
- DMA controller
- PDM stream processor
- 16 or 32 MHz crystal oscillator
- 32 kHz crystal oscillator
- Battery voltage and temperature sensors
- Average advertisement current consumption 15.34 µA (advertisement interval 1000 ms)
 - 1 year, 8 months, 19 days with 230 mAh battery (CR2032)
- Average connection current consumption 7.059 µA (connection interval 1000 ms)
 - 3 years, 10 months, 12 days with 230 mAh battery (CR2032)
- ST companion integrated balun/filter chips are available
- Up to +8 dBm available output power (at antenna connector)
- Excellent RF link budget (up to 96 dB)
- Accurate RSSI to allow power control
- 8.3 mA TX current (@ -2 dBm, 3.0 V)
- Down to 1 µA current consumption with active BLE stack (sleep mode)
- Suitable for building applications compliant with the following radio frequency regulations: ETSI EN 300 328, EN 300 440, FCC CFR47 Part 15, ARIB STD-T66
- Pre-programmed bootloader via UART
- QFN32, WCSP34 package option

Applications

- Watches
- Fitness, wellness and sports
- Consumer medical
- Security/proximity
- Remote control
- Home and industrial automation
- Assisted living
- Mobile phone peripherals
- Lighting
- PC peripherals

1 Description

The BlueNRG-1 is a very low power Bluetooth low energy (BLE) single-mode system-on-chip, compliant with Bluetooth specifications.

The BlueNRG-1 extends the features of award-winning BlueNRG network processor, enabling the usage of the embedded Cortex M0 to run the user's application code.

The BlueNRG-1 includes 160 kB of programming Flash memory, 24 kB of static RAM memory with retention (two 12 kB banks) and SPI, UART, I²C standard communication interface peripherals. It also features multifunction timers, watchdog, RTC and DMA controller.

An ADC is available to interface with analog sensors, and to read the measurement of the integrated battery voltage sensor. A digital filter is available to process a PDM stream.

The BlueNRG-1 offers the same excellent RF performance of the BlueNRG radio, and the integrated high efficiency DC-DC converter keeps the same ultra-low power characteristics, but the BlueNRG-1 improves the BlueNRG sleep mode current consumption allowing a further increase in the battery lifetime of the applications.

Figure 1: BlueNRG-1 architecture

Figure 2: BlueNRG-1 bus architecture

2 BlueNRG-1 Bluetooth low energy stack

The BlueNRG-1 is complemented with a Bluetooth low energy stack C library that provides:

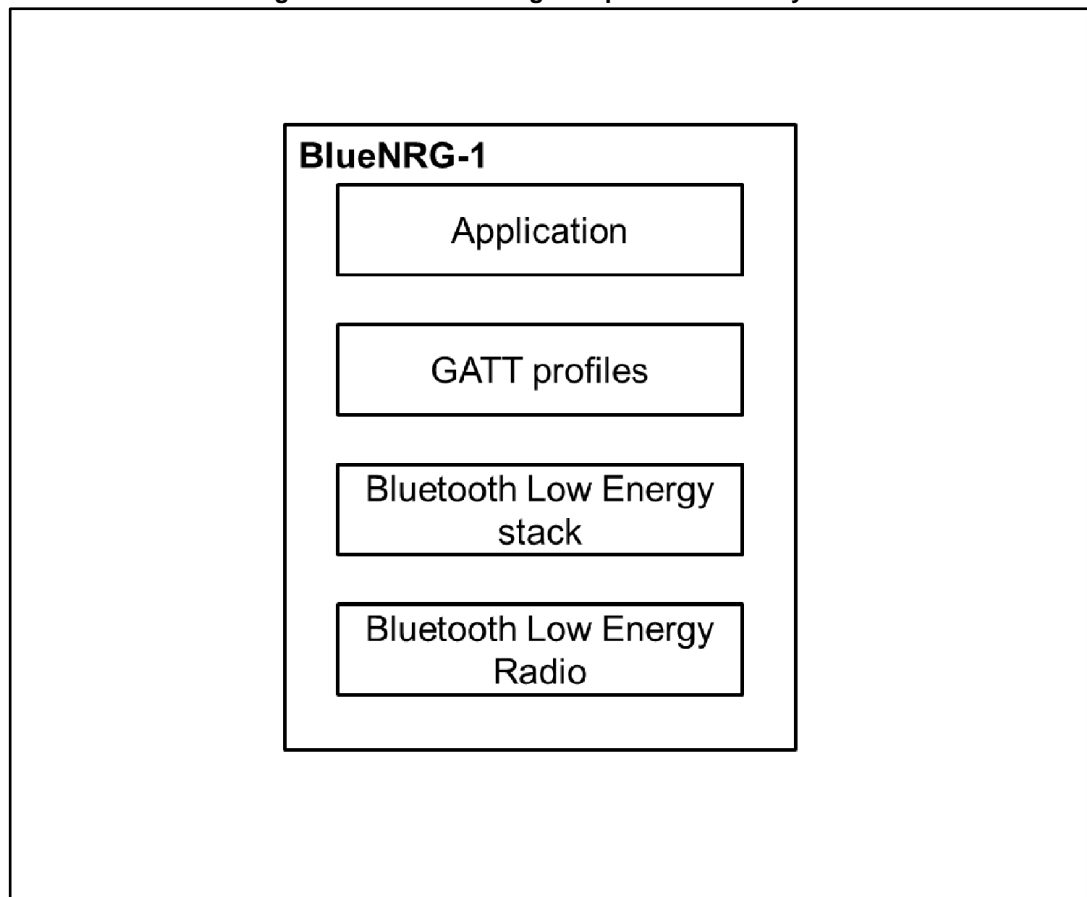

- Master, slave role support
- GAP: central, peripheral, observer or broadcaster roles
- ATT/GATT: client and server
- SM: privacy, authentication and authorization.
- L2CAP
- Link layer: AES-128 encryption and decryption

The BlueNRG-1 can be configured to support single-chip or network processor applications.

In the first configuration, the BlueNRG-1 operates as single device in the application for managing both the application code and the Bluetooth low energy stack. The whole Bluetooth low energy stack is provided as object code in a single library file whereas the GATT low energy profiles are provided as object codes in separate libraries.

Figure 3: "BlueNRG-1 single chip RF software layers" shows the single-chip RF software layers.

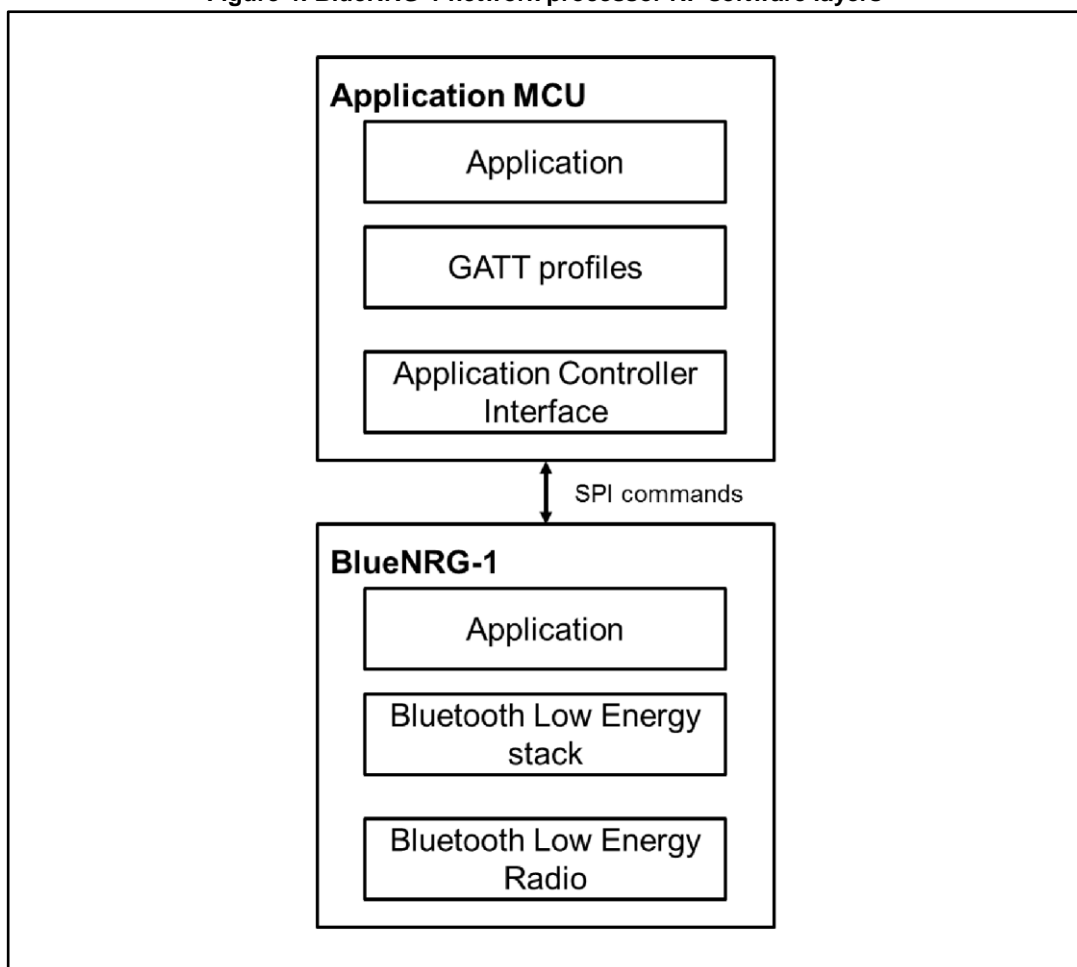

Figure 3: BlueNRG-1 single chip RF software layers

The BlueNRG-1 can be configured for operating as a network coprocessor. In this case a dedicated firmware is provided for supporting the interface with an external application

processor. The whole Bluetooth low energy stack runs in the BlueNRG-1; the GATT profiles are provided for running in the application processor together with the application code. Below figure shows the network processor RF software layers.

Figure 4: BlueNRG-1 network processor RF software layers

3 Functional details

The BlueNRG-1 integrates the blocks listed below:

- Cortex M0 core
- Interrupt management
- 160 kB Flash memory
- 24 kB of RAM with two retention options (12 kB or 24 kB)
- Power management
- Clocks
- Bluetooth low energy radio
- Random number generator (RNG) (it is reserved to Bluetooth low energy protocol stack, but user application can read it)
- Public key cryptography (PKA) (reserved to Bluetooth low energy protocol stack)
- Peripherals:
 - SPI interface
 - UART interface
 - I²C bus interface
 - GPIO
 - Multifunction timer
 - DMA controller
 - Watchdog
 - RTC
 - ADC with battery voltage sensor and temperature sensor
 - PDM stream processor

The main blocks are described in the following subsection.

3.1 Core

The ARM® Cortex®-M0 processor has been developed to provide a low-cost platform that meets the needs of MCU implementation, with a reduced pin count and low-power consumption, while delivering outstanding computational performance and an advanced system response to interrupts.

The ARM® Cortex®-M0 32-bit RISC processor features exceptional code-efficiency, delivering the high-performance expected from an ARM core in the memory size usually associated with 8-bit and 16-bit devices.

The BlueNRG-1 has an embedded ARM core and is therefore compatible with all ARM tools and software.

3.2 Interrupts

The Cortex-M0 nested vector interrupt controller (NVIC) handles interrupts. The NVIC controls specific Cortex-M0 interrupts (address 0x00 to 0x3C) as well as 32-user interrupts (address 0x40 to 0xBC). In the BlueNRG-1 device, the user interrupts are connected to the interrupt signals of the different peripherals.

Table 2: BlueNRG-1 interrupt vectors

Position	Priority	Priority type	Description	Address

24 – 31	Init 0	Settable	RESERVED	0x0000_00A0 – 0x0000_00BC

3.3 Memories

The memory subsystem consists of 160 kB Flash memory and two banks of 12 kB ultra-low leakage static RAM blocks.

The 160 kB Flash memory is available to the user and can be accessed per 32-bit for read access and per 32-bit for write access (with 4x32-bit FIFO).

The access to the static RAM can be as bytes, half words (16 bits) or words (32 bits).

A 12 kB RAM block is always in retention mode, whereas the second 12 kB RAM block is switchable and can be put in retention mode according to the user needs.

3.4 Power management

The BlueNRG-1 integrates both a low dropout voltage regulator (LDO) and a step-down DC-DC converter to supply the internal BlueNRG-1 circuitry.

The BlueNRG-1 most efficient power management configuration is with DC-DC converter active where best power consumption is obtained without compromising performances. Nevertheless, a configuration based on LDO can also be used, if needed.

A simplified version of the state machine is shown below.

Figure 5: BlueNRG-1 power management state machine

3.4.1 State description

3.4.1.1 Preactive state

The preactive state is the default state after a POR event.

In this state:

- All the digital power supplies are stable.
- The high frequency clock runs on internal fast clock RC oscillator (16 MHz).
- The low frequency clock runs on internal RC oscillator (32.768 kHz).

3.4.1.2 Active state

In this state:

- The high frequency runs on the accurate clock (16 MHz \pm 50 ppm) provided by the external XO. The internal fast clock RO oscillator is switched off.

If the external XO is at 32 MHz, some specific programming are needed, see [Section 3.5.3: "Switching to external clock"](#).

3.4.1.3 Standby state

In this state:

- Only the digital power supplies necessary to keep the RAM in retention are used.

The wake-up from this low power state is driven by the following sources:

- IO9
- IO10
- IO11
- IO12
- IO13^a

If they have been programmed as wake-up source in the system controller registers.

3.4.1.4 Sleep state

In this state:

- Only the digital power supplies necessary to keep the RAM in retention are used.
- The low frequency oscillator is switched on.

The wake-up from this low power state is driven by the following sources:

- IO9
- IO10
- IO11
- IO12
- IO13^a

If they have been programmed as wake-up source in the system controller registers and from the internal timers of the BLE radio.

3.4.1.5 IO wake-up sources

The IOs programmed to be wake-up sources need an external drive according to the selected level sensitivity.

If the wake-up level is high level, a pull-down drive should be used. If the wake-up level is low level, a pull-up drive should be used.

If no external drive is applied, IO9, IO10 and IO11 are only sensitive to low level as they have an internal pull-up (activated by default). IO12 and IO13 do not have an internal pull and therefore require an external drive.

3.4.1.6 Wake up time

The wake-up time is typically 200 μ s at 3.0 V and a temperature of 25°C.

^a Not available on WCSP34.

3.4.2 Power saving strategy

The application power saving strategy is based on clock stopping, dynamic clock gating, digital power supply switch off and analog current consumption minimization.

A summary of functional blocks versus the BlueNRG-1 states is provided below.

Table 3: Relationship between BlueNRG-1 states and functional blocks

Functional blocks	RESET	STANDBY	SLEEP	Preactive	Active	LOCK RX/ LOCK TX	RX	TX
LDO_SOFT_1V2 or LDO_SOFT_0V9	OFF	ON	ON	ON	ON	ON	ON	ON
LDO_STRONG_1V2	OFF	OFF	OFF	ON	ON	ON	ON	ON
LDO_DIG_1V8	OFF	OFF	OFF	ON	ON	ON	ON	ON
SMPS	OFF	OFF	OFF	ON	ON	ON	ON	ON
LDO_DIG_1V2	OFF	OFF	OFF	ON	ON	ON	ON	ON
BOR	OFF	ON	ON	ON	ON	ON	ON	ON
16 MHz RO	OFF	OFF	OFF	ON	OFF	OFF	OFF	OFF
16 MHz XO	OFF	OFF	OFF	OFF	ON	ON	ON	ON
32 kHz RO or XO	OFF	OFF	ON	ON	ON	ON	ON	ON

3.4.3 System controller registers

SYSTEM_CTRL peripheral base address (SYSTEM_CTRL_BASE_ADDR) 0x40200000.

Table 4: SYSTEM_CTRL registers

Address offset	Name	RW	Reset	Description
0x00	WKP_IO_IS	RW	0x00000000	Level selection for wake-up IO (1 bit for IO). 0: The system wakes up when IO is low. 1: The system wakes up when IO is high.
0x04	WKP_IO_IE	RW	0x00000007	Enables the IO that wakes up the device (1 bit for IO). 0: The wake-up feature on the IO is disabled. 1: The wake-up feature on the IO is enabled.
0x08	CTRL	RW	0x00000000	XO frequency indication is provided by the application. Refer to the detailed description below.

31:1	RESERVED	0x0	RW	RESERVED

AHBUPCONV peripheral base address (AHBUPCONV_BASE_ADDR) 0x40C00000.

Table 8: AHBUPCONV registers

Address offset	Name	RW	Reset	Description
0x00	COMMAND	RW	0x00000000	AHB up/down converter command register

BLUE_CTRL peripheral base address (BLUE_CTRL_BASE_ADDR) 0x48000000.

Table 9: BLUE_CTRL registers

Address offset	Name	RW	Reset	Description
0x04	TIMEOUT	RW	0x00000000	Timeout programming register
0x0C	RADIO_CONFIG	RW	0x00000000	Radio configuration register

All RESERVED fields inside registers must always be written with their default value.

3.5 Clocks and reset management

The BlueNRG-1 embeds an RC low-speed frequency oscillator at 32 kHz and an RO high-speed frequency oscillator at 16 MHz.

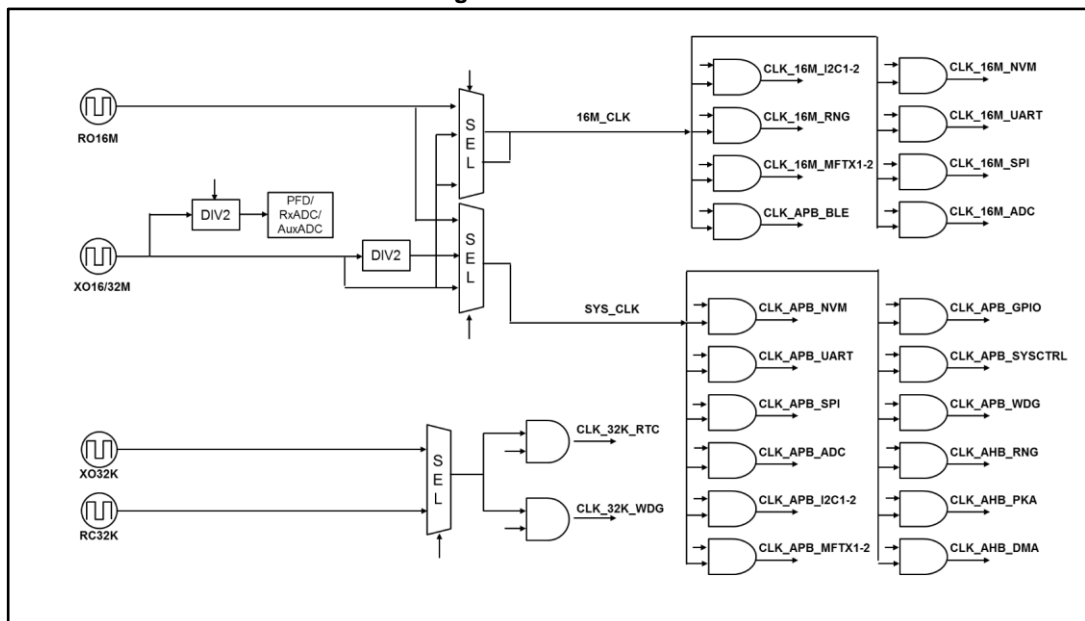

The low-frequency clock is used in low power mode and can be supplied either by a 32.7 kHz oscillator that uses an external crystal and guarantees up to ± 50 ppm frequency tolerance, or by a ring oscillator with maximum ± 500 ppm frequency tolerance, which does not require any external components.

The primary high-speed frequency clock is a 16 MHz or 32 MHz crystal oscillator. A fast-starting 16 MHz ring oscillator provides the clock while the crystal oscillator is starting up. Frequency tolerance of high-speed crystal oscillator is ± 50 ppm.

The usage of the 16 MHz^a (or 32 MHz) crystal is strictly necessary for RF communications.

The clock tree for the peripherals is as follows:

Figure 6: Clock tree

^a For constraints related to the 16 MHz high-speed crystal usage, refer to the BlueNRG-1 DK SW release notes.

When 32 MHz XO is used, the Cortex-M0, the DMA and the APB tree (except for BLE radio access) run at 32 MHz. The rest of the clock tree is divided by two and is at 16 MHz.

The following clocks can be enabled/disabled by software to implement optimal power consumption:

- DMA
- BLE controller
- BLE clock generator
- RNG
- Flash controller
- GPIO
- System controller
- UART
- SPI
- I2C1^a
- I2C2
- ADC
- MFT1
- MFT2
- RTC
- WDG
- PKA

By default, all the peripheral APB and AHB clocks are enabled, except for the PKA peripheral. The following clocks are enabled/disabled automatically:

- Processor clock (disabled in sleep mode)
- RAM clock (disabled if processor clock, SPI clock and BLE clock are all disabled)

3.5.1 Reset management

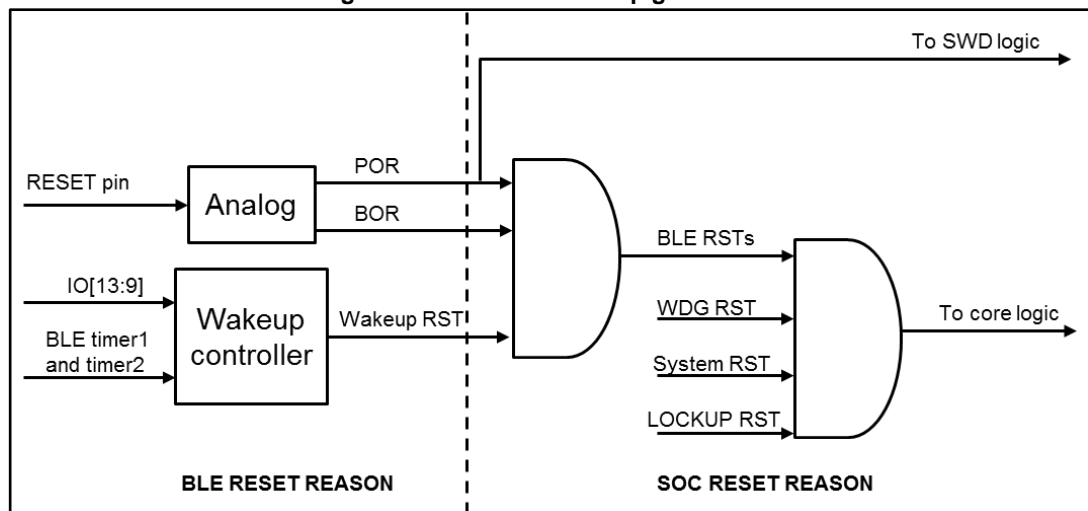

Figure 7: "Reset and wake-up generation" shows the general principle of reset. Releasing the Reset pin puts the chip out of shutdown state. The wakeup logic is powered and receives the POR. Each time the wake-up controller decides to exit sleep or standby modes, it will generate a reset for the core logic. The core logic can also be reset by:

- Watchdog
- Reset request from the processor (system reset)
- LOCKUP state of the Cortex-M0

The SWD logic is reset by the POR. It is important to highlight that reset pin actually power down chip, so it is not possible to perform debug access with system under reset.

^a The I²C1 is not available in WLCSP34 package.

Figure 7: Reset and wake-up generation

If, for any reason, the users would like to power off the device there are two options:

1. Force RESETN pin to ground, keeping VBAT level
2. To put VBAT pins to ground (e.g. via a transistor)

In the second option, care must be taken to ensure that no voltage is applied to any of the other pins since device can be powered and having an anomalous power consumption. ST recommendation is to use RESETN whenever it is possible.

3.5.1.1 Power-on-Reset

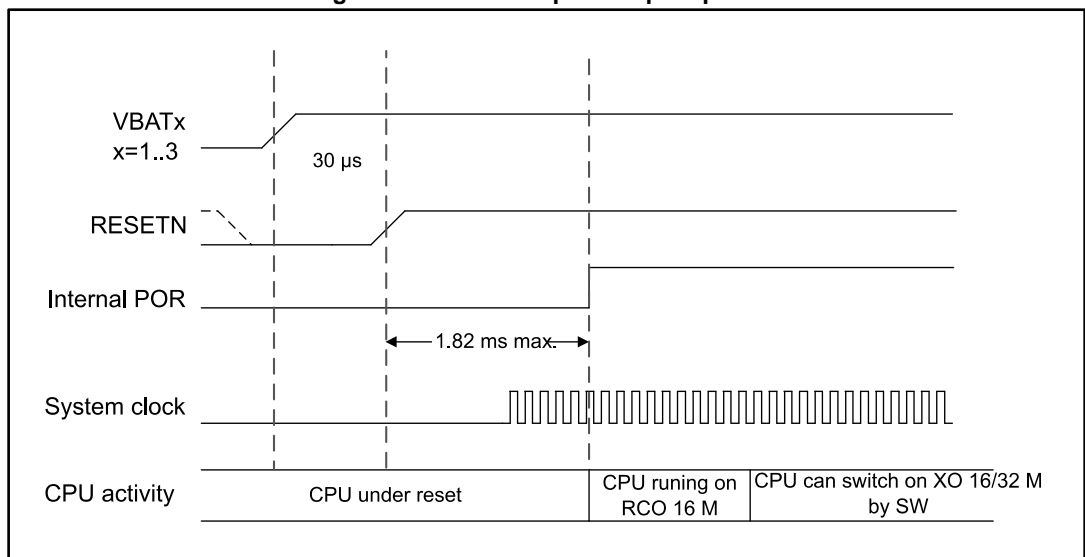

The Power-on-Reset (POR) signal is the combination of the POR signal and the BOR signal generated by the analog circuitry contained in the BlueNRG-1 device. The combination of these signals is used to generate the input to the Cortex-M0, which is used to reset the debug access port (DAP) of the processor. It is also used to generate the signal, which resets the debug logic of the Cortex-M0. The POR signal also resets the TAP controller of the BlueNRG-1 and a part of the Flash controller (managing the Flash memory boot, which does not need to be impacted by system resets).

The BOR is disabled by default, see the BlueNRG-1, BlueNRG-2 BLE stack programming guidelines (PM0257) to enable it.

3.5.1.2 Power-on-sequence

The starting sequence of the BlueNRG-1 supply and reset signal is shown below.

Figure 8: BlueNRG-1 power-up sequence

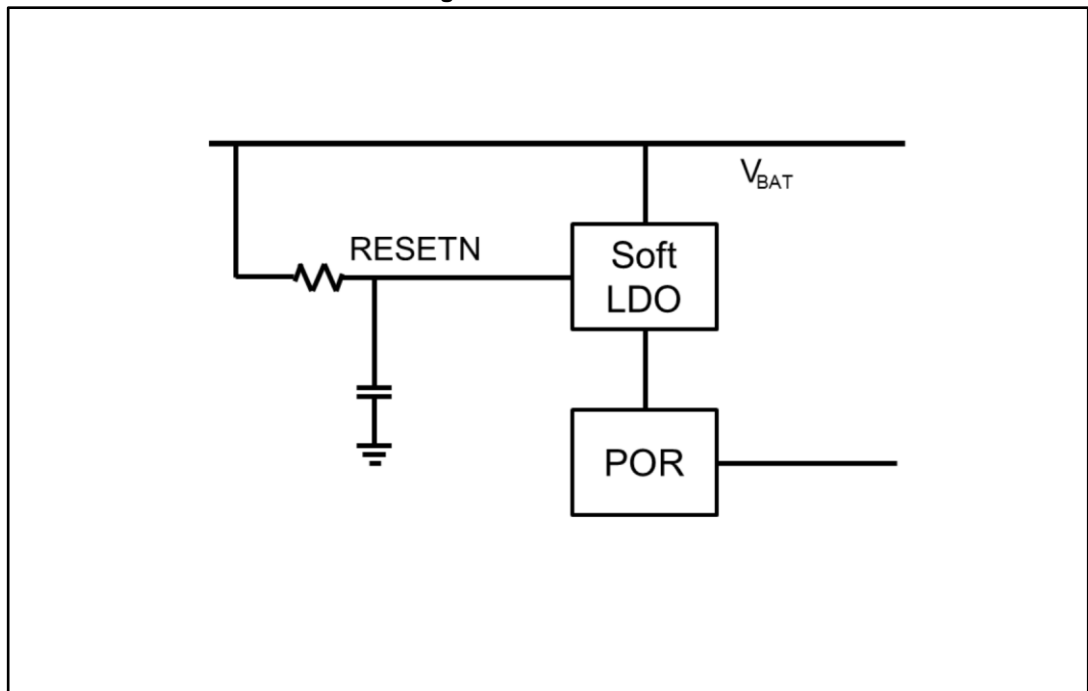

- The VBATx power must only be raised when RESETN pin is driven low.
- The different VBATx (x=1..3) power can be raised separately or together.
- The internal POR is released once internal LDOs are established and RCO clock is ready.
- The system starts on RCO 16 MHz clock system. The software is responsible for configuring the XO 16/32 MHz when necessary.

Note that: the minimum negative pulse to reset the system must be at least 30 μs.

The POR circuit is powered by a 1.2 V regulator, which must also be powered up with the correct startup sequence. Before VBAT has reached the nominal value, RESETN line must be kept low. An external RC circuit on RESETN pin will add a delay that can prevent RESETN signal from going high before VBAT has reached the nominal value.

Figure 9: Reset circuit

If the above conditions are not satisfied, ST cannot guarantee the correct operation of the device.

3.5.1.3 Watchdog reset

The BlueNRG-1 contains a watchdog timer, which may be used to recover from software crashes. The watchdog contains a 32-bit down counter, which generates an interrupt, if the interrupt is not serviced, the watchdog will generate a reset. The watchdog reset resets the Flash controller, the Cortex-M0 and all its peripherals but it does not reset the debug circuitry of the Cortex-M0.

3.5.1.4 System reset request

The system reset request is generated by the debug circuitry of the Cortex-M0. The debugger writes to the SYSRESETREQ bit of the “application interrupt and reset control register” (AIRCR). This system reset request through AIRCR register can also be done by embedded software. The system reset request does not affect the debugger, thus allowing the debugger to remain connected during the reset sequence.

3.5.1.5 Lock-up reset

The Cortex-M0 generates an output LOCKUP that indicates that the core is in a deliberate lock-up state resulting from an unrecoverable exception. The LOCKUP signal is used to generate a reset in the BlueNRG-1, which affects the Cortex-M0, the Flash controller and all the peripherals.

The LOCKUP signal does not reset the Cortex-M0 debug circuitry and it is not generated if a debugger is connected.

3.5.2 Reset and wake-up reason decoding

The BlueNRG-1 provides a set of registers to identify the reason behind a reset and wakeup generation. Two registers are used: CKGEN_SOC->REASON_RST and CKGEN_BLE->REASON_RST. The possible reasons are listed below:

1. If the register CKGEN_SOC->REASON_RST = 0, according to the CKGEN_BLE->REASON_RST the possible reasons are:
 - a. Wake-up from IO9, IO10, IO11, IO12, IO13.
 - b. Wake-up from internal timer: BLE timer 1 or BLE timer 2.
 - c. POR or BOR
2. If the register CKGEN_SOC->REASON_RST is not 0, according to its value the possible reasons are:
 - a. System reset
 - b. Watchdog reset
 - c. Lockup reset.

3.5.3 Switching to external clock

When the system is in preactive state (run from internal RO 16 MHz), the software sequence to switch to active should include switch to external XO.

When the system uses an external XO at 32 MHz instead of 16 MHz, the following steps need to be performed:

1. Set the bitfield MHZ32_SEL of register SYSTEM_CTRL for the digital part.
2. In the preactive state, inform the analog part of the external XO 32 MHz and send the request to switch to ACTIVE2 state:

```
uint8_t config[] = { 0x02, 0x3A, 0x44, 0x02, 0x34, 0x1B, 0x00};
BLUE_CTRL->RADIO_CONFIG = 0x10000 | (uint16_t) ( (uint32_t)config &
```

- ```
0x0000FFFF);
while((BLUE_CTRL->RADIO_CONFIG & 0x10000) != 0);
```
- Wait until the state machine is in the active state by using the following routine:

```
while(CKGEN_BLE->CLK32K_IT == 0);
CKGEN_BLE->CLK32K_IT = 1;
CKGEN_BLE->CLK32K_COUNT = 23;
CKGEN_BLE->CLK32K_PERIOD = 0;
```
  - Only after switching to the active state, write 0x15 in the COMMAND register of the AHBUPCONV peripheral.

Around 10 system clock cycles after this last write, the system will run at 32 MHz except for specific blocks requiring a fixed 16 MHz.

The application can make the bus and the core run at 16 MHz by writing 0x14 in the COMMAND register of AHBUPCONV peripheral.

### 3.5.4 Clock and reset registers

CKGEN\_SOC peripheral base address (CKGEN\_SOC\_BASE\_ADDR) 0x40900000.

Table 10: CKGEN\_SOC registers

## 3.6 ADC

### 3.6.1 Introduction

The BlueNRG-1 integrates a 10-bit analog-to-digital converter (ADC) for sampling an external signal.

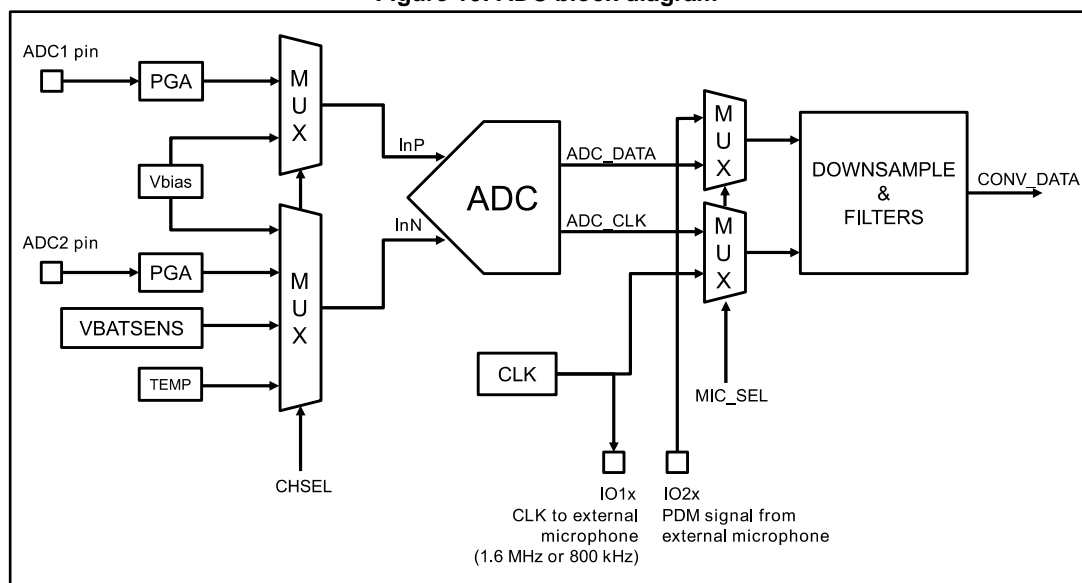

Main features are:

- Sampling frequency 1 MHz
- One channel in single ended or differential input through the pins ADC1 and ADC2
- Temperature and battery voltage sensors
- The conversion are either continuous or single step acquisition
- An integrated digital filter is used to process a PDM data stream from a MEMS microphone

### 3.6.2 Functional overview

The figure below shows a top diagram of the ADC.

Figure 10: ADC block diagram

Several channels are available for the conversion, the CHSEL selects the channel according to [Table 21: "ADC channels"](#).

Table 21: ADC channels

| CHSEL | Channels description                                                  |
|-------|-----------------------------------------------------------------------|
| 0     | All switch open. No input                                             |
| 1     | Single ended through ADC2 pin. InP = Vbias (internal), InN = ADC2 pin |
| 2     | Single ended through ADC1 pin. InP = ADC1 pin, InN = Vbias (internal) |
| 3     | Differential ADC1 pin – ADC2 pin. InP = ADC1 pin, InN = ADC2 pin      |
| 4     | Temperature sensor. InN=TEMP, InP = 0.6 V (internal)                  |
| 5     | Battery voltage sensor. InN = VBATSENS, InP = 0.6 V (internal)        |
| 6     | Short. InP = InN = 0.6 V (internal)                                   |

The conversion can be single (CONT = 0) or continuous (CONT = 1). In continuous mode, the conversion runs with a pre-programmed sampling rate, while in single step mode the ADC performs a conversion and then stops.

The output data rate depends on the setting of OSR according to the following table.

Table 22: ADC data rate

| OSR     | Output data rate [Ksample/s] |
|---------|------------------------------|
| 0 (200) | 5                            |
| 1 (100) | 10                           |
| 2 (64)  | 15.625                       |
| 3 (32)  | 31.25                        |

The setting of the oversampling ratio (OSR) must be done according to the frequency of the input signal (AC), while for DC signals, the best performance is with OSR = 200. In order to achieve the best performance within the selected input voltage range, the

attenuation value must be set through the corresponding register PGASEL value, as in the following table.

**Table 23: ADC parameter settings**

| Vin range [V] | Vbias [V] | Attenuation [dB] | REFSEL value | PGASEL value |
|---------------|-----------|------------------|--------------|--------------|
| [0, 1.2]      | 0.6       | 0                | 2            | 0            |
| [0, 2.4]      | 0.6       | 6.02             | 2            | 1            |
| [0, 3.6]      | 0.6       | 9.54             | 2            | 2            |

The system can work in conjunction with an external MEMS microphone by setting MIC\_SEL. In this mode, an IO configured as PDM\_CLK provides the clock to the external microphone, while an IO configured as PDM\_DATA received the PDM stream from the external microphone. The external clock is 1.6 MHz (DIG\_FILT\_CLK = 0) or 0.8 MHz (DIG\_FILT\_CLK = 1).

The output data rate changes with the OSR according to [Table 24: "Output data rate with microphone"](#).

**Table 24: Output data rate with microphone**

| DIG_FILT_CLK        | OSR     | Output data rate [Ksample/s] |
|---------------------|---------|------------------------------|
| 1 (clock = 0.8 MHz) | 0 (200) | 4                            |
|                     | 1 (100) | 8                            |
|                     | 2 (64)  | 12.5                         |
|                     | 3 (32)  | 25                           |
| 0 (clock = 1.6 MHz) | 0 (200) | 8                            |
|                     | 1 (100) | 16                           |
|                     | 2 (64)  | 25                           |
|                     | 3 (32)  | 50                           |

### 3.6.2.1 ADC start conversion

The ADC both analog and digital sub-system are switched on by setting ADCON and SWSTART.

The conversion operation consists of four phases.

1. The wake-up phase lasts 6  $\mu$ s, is present at the beginning of a single acquisition, with the goal to let the analog system to settle before to start the acquisition.
2. If the CALEN is set, a calibration phase is performed. It permits to compensate the offset in the analog part. The conversion status is tracked by SR status register. At the beginning of the conversion the BUSY bit is set and masks any attempt to change CONF, up to the end of the conversion. At end of this conversion, the ENDCAL flag is generated and the OFFSET register is written with the converted offset voltage.
3. The acquisition phase is regulated by a timeout depending on the resolution. In this phase, digital filter chain processes the data coming from ADC.
4. The elaboration phase is at the end of the timeout, the data obtained at the output of the digital filter is written in the DATA register. If the calibration is on, the output of the digital filter is de-embedded considering the content of the OFFSET register. Furthermore, the ADCEOC flag is generated to warn about the end of conversion. If ENAB\_COMP bit is set, the WDOG flag is generated to warn that the result of the conversion is between a high THRESHOLD\_HI and low threshold THRESHOLD\_LO.

It is always advisable to set the register field CALEN in order to perform automatic calibration for each measurement.

### 3.6.2.2 ADC offset

The ADC can automatically correct the offset error.

To enable the automatic offset correction the CALEN and the OFFSET\_UPDATE must be set. The result of the last calibration is stored in the OFFSET register.

The correction of the offset can be also done manually, for example by making a conversion of the internal channel  $INP = INN = 0.6\text{ V}$  and after that, writing the result of conversion in the OFFSET register.

### 3.6.2.3 ADC conversion

The relationship between differential input voltage and  $ADC_{RAW}$  code (first 16-bit MSB of  $ADC\_CONV$  register) depends on a limited set of parameters: the digital reference voltage  $V_{REF}$ , the PGA value, and a scaling factor.

#### Differential mode

$$V_{ADC12(Volt)} = V_{ADC1} - V_{ADC2} = (1 + PGASEL) * \left( \frac{ADC_{RAW}}{FS_{16(OSR)}} \right) * V_{REF}$$

With:

- PGASEL is the input attenuation register, values: 0, 1 or 2.
- $ADC_{RAW}$  is the value  $ADC\_CONV[31:16]$ .
- $FS_{16(OSR)}$  is the full scale factor for  $ADC_{RAW}$  it depends on the oversampling ratio (OSR):
  - $FS_{16(32)} = FS_{16(64)} = 16708$
  - $FS_{16(100)} = FS_{16(200)} = 19450$
- $V_{REF}$  represents the digital core power supply, typical  $V_{REF}$  value is 2.4 V.

#### Single-ended mode

$$V_{ADC1(Volt)} = (1 + PGASEL) * (V_{bias} + \left( \frac{ADC_{RAW}}{FS_{16(OSR)}} \right) * V_{REF}$$

$$V_{ADC2(Volt)} = (1 + PGASEL) * (V_{bias} - \left( \frac{ADC_{RAW}}{FS_{16(OSR)}} \right) * V_{REF}$$

With:

- PGASEL is the input attenuation register, values: 0, 1 or 2.
- $ADC_{RAW}$  is the value  $ADC\_CONV[31:16]$ .
- $FS_{16(OSR)}$  is the full scale factor for  $ADC_{RAW}$  it depends on the oversampling ratio (OSR):
  - $FS_{16(32)} = FS_{16(64)} = 16708$
  - $FS_{16(100)} = FS_{16(200)} = 19450$
- $V_{REF}$  represents the digital core power supply, typical  $V_{REF}$  value is 2.4 V.
- $V_{bias}$  is given by the register REFSEL, with a typical value of 0.6 V.

#### Battery voltage sensor

$$V_{BATT(Volt)} = K_{BATT} * (V_{bias} - \left( \frac{ADC_{RAW}}{FS_{16(OSR)}} \right) * V_{REF})$$

This mode enables the monitoring of the battery voltage  $V_{BATT}$ , through an internal resistive bridge.

With:

- $ADC_{RAW}$  is the value  $ADC\_CONV[31:16]$ .
- $FS\_16(OSR)$  is the full scale factor for  $ADC_{RAW}$  it depends on the oversampling ratio (OSR):
  - $FS\_16(32) = FS\_16(64) = 16708$ .
  - $FS\_16(100) = FS\_16(200) = 19450$
- $V_{REF}$  represents the digital core power supply, typical  $V_{REF}$  value is 2.4 V.
- $V_{bias}$  is given by the register  $REFSEL$ , with a typical value of 0.6 V.
- $K_{BATT}$  is 4.36.

#### Temperature sensor

This mode enables the monitoring of the temperature by means of an internal sensor, with the following voltage to temperature conversion:

$$V_{TEMP(^{\circ}C)} = K_{TC} * (V_{bias} - \left(\frac{ADC_{RAW}}{FS\_16(OSR)}\right) * V_{REF}) + OFFSET_{TC}$$

With:

- $ADC_{RAW}$  is the value  $ADC\_CONV[31:16]$ .
- $FS\_16(OSR)$  is the full scale factor for  $ADC_{RAW}$  it depends on the oversampling ratio (OSR):
  - $FS\_16(32) = FS\_16(64) = 16708$
  - $FS\_16(100) = FS\_16(200) = 19450$
- $V_{REF}$  represents the digital core power supply, typical  $V_{REF}$  value is 2.4 V.
- $V_{bias}$  is given by the register  $REFSEL$ , with a typical value of 0.6 V.
- $K_{TC}$  is 401
- $OFFSET_{TC}$  is -267 °C

To ensure an accurate temperature reading, average the value over several reads.

### 3.6.3 ADC registers

ADC peripheral base address ( $ADC\_BASE\_ADDR$ ) 0x40800000.

Table 25: ADC registers

| Address offset | Name      | RW | Reset      | Description                                                                  |
|----------------|-----------|----|------------|------------------------------------------------------------------------------|
| 0x00           | CTRL      | RW | 0x00000000 | ADC control register. Refer to the detailed description below.               |
| 0x04           | CONF      | RW | 0x0000000C | ADC configuration register. Refer to the detailed description below.         |
| 0x08           | IRQSTAT   | R  | 0x00000000 | IRQ masked status register. Refer to the detailed description below.         |
| 0x0C           | IRQMASK   | RW | 0x0000000F | It sets the mask for ADC interrupt. Refer to the detailed description below. |
| 0x14           | DATA_CONV | R  | 0x00000000 | Result of the conversion in two complement format.                           |

| Address offset | Name         | RW | Reset      | Description                                                   |
|----------------|--------------|----|------------|---------------------------------------------------------------|
| 0x18           | OFFSET       | RW | 0x00000000 | Offset for correction of converted data                       |
| 0x20           | SR_REG       | RW | 0x00000000 | ADC status register. Refer to the detailed description below. |
| 0x24           | THRESHOLD_HI | RW | 0xFFFFFFFF | High threshold for window comparator.                         |
| 0x28           | THRESHOLD_LO | RW | 0x00000000 | Low threshold for window comparator.                          |

Table 26: ADC - CTRL register description: address offset ADC\_BASE\_ADDR+0x00

| Bit   | Field name  | Reset | RW | Description                                                                                                                                                                                                                                                      |
|-------|-------------|-------|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | ON          | 0x0   | RW | Starts ADC analog subsystem. This bit must be set before starting a conversion.<br>0: ADC is OFF.<br>1: ADC is ON.                                                                                                                                               |
| 1     | CALEN       | 0x0   | RW | Enables the calibration phase when set to 1. This bit is cleared and the calibration is disabled by setting the RSTCALEN bit.                                                                                                                                    |
| 2     | SWSTART     | 0x0   | RW | Starts the ADC conversion phase when set.                                                                                                                                                                                                                        |
| 3     | RESET       | 0x0   | RW | Reset all the ADC registers when set. This bit is auto-cleared by the hardware so it is always read at 0                                                                                                                                                         |
| 4     | STOP        | 0x0   | RW | Permits the continuous conversion to be stopped.<br>0: continuous conversion is enabled but SWSTART and ADCON bits must be set.<br>1: stop the continuous conversion and switch off the ADC. This bit is auto-cleared by the hardware so it is always read at 0. |
| 5     | ENAB_COMP   | 0x0   | RW | Enables the window comparator when set to 1. WDOG flag is ADC_SR register is set if the converted value is between THRESHOLD_HI and THRESHOLD_LO value.                                                                                                          |
| 6     | RSTCALEN    | 0x0   | RW | Disable the calibration phase when set to 1. This bit has to be set to disable the calibration each time calibration is enabled. This bit is auto-cleared by the hardware so it is always read at 0.                                                             |
| 7     | AUTO_OFFSET | 0x0   | RW | Enables the update of OFFSET register.<br>0: OFFSET register is not updated.<br>1: OFFSET register is updated.                                                                                                                                                   |
| 8     | MIC_ON      | 0x0   | RW | Enables the filter chain for voice when set to 1.<br>0: Filter chain is disabled.<br>1: Filter chain is enabled.                                                                                                                                                 |
| 9     | DMA_EN      | 0x0   | RW | Enables the DMA.<br>0: DMA is disabled.<br>1: DMA is enabled.                                                                                                                                                                                                    |

## 3.7 DMA

### 3.7.1 Introduction

The BlueNRG-1 device embeds a DMA allowing various combination of data transfer between the memory and the peripherals without CPU intervention.

Main features are:

- Eight independently configurable channels connected to dedicated hardware DMA requests; software trigger is also supported.
- Priorities between requests from channels of the DMA are software programmable (four levels consisting of very high, high, medium, low). When two channels with same software priority need attention, channel with lower hardware index will take priority.
- Independent source and destination transfer size (byte, half word, word), emulating packing and unpacking.
- Support for circular buffer management.
- Event flags (DMA half transfer, DMA transfer complete), logically ORed together in a single interrupt request for each channel.

- Memory-to-memory transfer (RAM only), peripheral-to-memory and memory-to-peripheral, and peripheral-to-peripheral transfers.
- Programmable number of data to be transferred up to 65536 bytes.

### 3.7.2 Functional overview

The DMA controller performs direct memory transfer by sharing the system bus with the other masters of the device. The DMA request may stop the CPU access to the system bus for some bus cycles, when the CPU and DMA are targeting the same destination (memory or peripheral). The bus matrix implements round-robin scheduling, thus ensuring at least half of the system bus bandwidth (both to memory and peripheral) for the CPU.

#### 3.7.2.1 DMA transactions

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, the DMA controller sends an acknowledge to the peripheral. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller. Once the request is deasserted by the peripheral, the DMA controller releases the acknowledge. If there are more requests, the peripheral can initiate the next transaction.

In summary, each DMA transfer consists of three operations:

- The loading of data from the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the DMA\_CPARx or DMA\_CMARx register
- The storage of the data loaded to the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the DMA\_CPARx or DMA\_CMARx register
- The post-decrementing of the DMA\_CNDTRx register, which contains the number of transactions that have still to be performed.

#### 3.7.2.2 Arbiter

The arbiter manages the channel requests based on their priority and launches the peripheral/memory access sequences.

The priorities are managed in two stages:

- Software: each channel priority can be configured in the DMA\_CCRx register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: if two requests have the same software priority level, the channel with the lowest number has the priority versus the channel with the highest number. For example, channel 2 gets priority over channel 4.

#### 3.7.2.3 DMA channels

Each channel can handle DMA transfer between a peripheral register located at a fixed address and a memory address. The amount of data to be transferred (up to 65535) is programmable. The register, which contains the amount of data items to be transferred, is decremented after each transaction.

### Programmable data sizes

Transfer data sizes of the peripheral and memory are fully programmable through the PSIZE and MSIZE bits in the DMA\_CCRx register.

### Pointer increments

Peripheral and memory pointers can optionally be automatically post-incremented after each transaction depending on the PINC and MINC bits in the DMA\_CCRx register. If incremented mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1, 2 or 4 depending on the chosen data size. The first transfer address is the one programmed in the DMA\_CPARx/DMA\_CMARx registers. During transfer operations, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software. If the channel is configured in non-circular mode, no DMA request is served after the last transfer (that is once the number of data items to be transferred has reached zero). In order to reload a new number of data items to be transferred into the DMA\_CNDTRx register, the DMA channel must be disabled.

If a DMA channel is disabled, the DMA registers are not reset. The DMA channel registers (DMA\_CCRx, DMA\_CPARx and DMA\_CMARx) retain the initial values programmed during the channel configuration phase.

In circular mode, after the last transfer, the DMA\_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA\_CPARx/DMA\_CMARx registers.

### Channel configuration procedure

The following sequence should be followed to configure a DMA channelx (where x is the channel number).

1. Set the peripheral register address in the DMA\_CPARx register. The data are moved from/ to this address to/ from the memory after the peripheral event.
2. Set the memory address in the DMA\_CMARx register. The data will be written to or read from this memory after the peripheral event.
3. Configure the total number of data to be transferred in the DMA\_CNDTRx register. After each peripheral event, this value is decremented.
4. Configure the channel priority using the PL[1:0] bits in the DMA\_CCRx register.
5. Configure data transfer direction, circular mode, peripheral and memory incremented mode, peripheral and memory data size, and interrupt after half and/or full transfer in the DMA\_CCRx register.
6. Activate the channel by setting the ENABLE bit in the DMA\_CCRx register.

As soon as the channel is enabled, it can serve any DMA request from the peripheral connected on the channel. Once half of the bytes are transferred, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

### Circular mode

Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA\_CCRx register. When circular mode is activated, the number of data to be transferred is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This mode is called memory-to-memory mode. If the MEM2MEM bit in the DMA\_CCRx

register is set, then the channel initiates transfers as soon as it is enabled by software by setting the Enable bit (EN) in the DMA\_CCRx register. The transfer stops once the DMA\_CNDTRx register reaches zero. Memory-to-Memory mode may not be used at the same time as Circular mode.

### 3.7.2.4 Programmable data width, data alignment and endianness

When PSIZE and MSIZE are not equal, the DMA performs some data alignments as described in [Table 35: "Programmable data width and endian behavior \(when bits PINC = MINC = 1\)"](#): Programmable data width & endian behavior (when bits PINC = MINC = 1).

**Table 35: Programmable data width and endian behavior (when bits PINC = MINC = 1)**

| Source port width | Destination port width | Number of data items to transfer (NDT) | Source content: address/data | Transfer operations                                    | Destination content: address/data |
|-------------------|------------------------|----------------------------------------|------------------------------|--------------------------------------------------------|-----------------------------------|

The DMA is addressed through AHB and can be accessed only with 32-bit access. Any 8-bit or 16-bit access will generate a hard fault.

When the DMA initiates an AHB byte or halfword write operation, the data are duplicated on the unused lanes of the HWDATA[31:0] bus. So when the used AHB slave peripheral

does not support byte or halfword write operations (when HSIZE is not used by the peripheral) and does not generate any error, the DMA writes the 32 HWDATA bits as shown in the two examples below:

- To write the halfword “0xABCD”, the DMA sets the HWDATA bus to “0xABCDABCD” with HSIZE = HalfWord
- To write the byte “0xAB”, the DMA sets the HWDATA bus to “0xABABABAB” with HSIZE = byte

Assuming that the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take the HSIZE data into account, it will transform any AHB byte or halfword operation into a 32-bit APB operation in the following manner:

- an AHB byte write operation of the data “0xB0” to 0x0 (or to 0x1, 0x2 or 0x3) is converted to an APB word write operation of the data “0xB0B0B0B0” to 0x0
- an AHB half-word write operation of the data “0xB1B0” to 0x0 (or to 0x2) is converted to an APB word write operation of the data “0xB1B0B1B0” to 0x0

### 3.7.2.5 Error management

A DMA transfer error can be generated by reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or a write access, the faulty channel is automatically disabled through a hardware clear of its EN bit in the corresponding channel configuration register (DMA\_CCRx). The channel's transfer error interrupt flag (TEIF) in the ISR register is set and an interrupt is generated if the transfer error interrupt enable bit (TEIE) in the DMA\_CCRx register is set.

### 3.7.2.6 Interrupts

An interrupt can be produced on a half-transfer, transfer complete or transfer error for each DMA channel. Separate interrupt enable bits are available for flexibility.

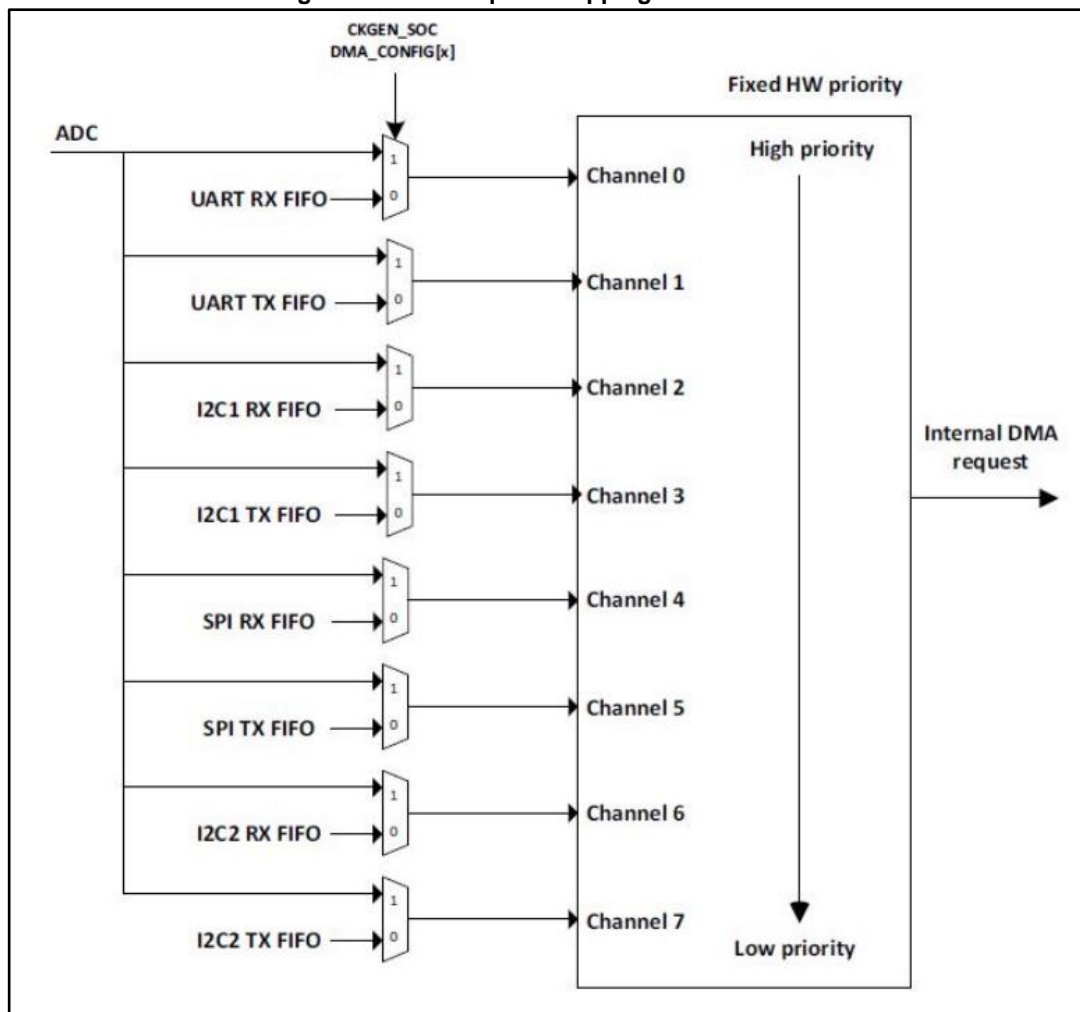

**Table 36: DMA interrupt requests**

| Interrupt event   | Event flag | Enable control bit |
|-------------------|------------|--------------------|
| Half-transfer     | HTIF       | HTIE               |
| Transfer complete | TCIF       | TCIE               |
| Transfer error    | TEIF       | TEIE               |

### 3.7.2.7 DMA request mapping

The eight requests from the peripherals (SPI, I2Cx[1,2] and UART) are multiplexed before entering DMA with the ADC request. For each channel, the choice between the peripheral and the ADC is done through the DMA\_CONFIG register.

Figure 11: DMA request mapping in BlueNRG-1

### 3.7.3 DMA registers

DMA peripheral base address (DMA\_BASE\_ADDR) 0xA0000000.

Table 37: DMA registers

| Address offset | Name | RW | Reset      | Description                                                                 |
|----------------|------|----|------------|-----------------------------------------------------------------------------|
| 0x00           | ISR  | R  | 0x00000000 | DMA interrupt status register. Refer to the detailed description below.     |
| 0x04           | IFCR | W  | 0x00000000 | DMA interrupt flag clear register. Refer to the detailed description below. |

Table 38: DMA - ISR register description: address offset DMA\_BASE\_ADDR+0x00

| Bit | Field name | Reset | RW | Description                                                                                                                                                                                                                                  |
|-----|------------|-------|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | GIF0       | 0x0   | R  | Channel 0 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 0.<br>1: A TE, HT or TC event occurred on channel 0. |

| Bit | Field name | Reset | RW | Description                                                                                                                                                                                                                                           |
|-----|------------|-------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | TCIF0      | 0x0   | R  | Channel 0 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 0.<br>1: A transfer complete (TC) occurred on channel 0. |
| 2   | HTIF0      | 0x0   | R  | Channel 0 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 0.<br>1: A half transfer (HT) event occurred on channel 0. |
| 3   | TEIF0      | 0x0   | R  | Channel 0 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 0.<br>1: A transfer error (TE) occurred on channel 0.    |
| 4   | GIF1       | 0x0   | R  | Channel 1 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 1.<br>1: A TE, HT or TC event occurred on channel 1.          |
| 5   | TCIF1      | 0x0   | R  | Channel 1 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 1.<br>1: A transfer complete (TC) occurred on channel 1. |
| 6   | HTIF1      | 0x0   | R  | Channel 1 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 1.<br>1: A half transfer (HT) event occurred on channel 1. |
| 7   | TEIF1      | 0x0   | R  | Channel 1 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 1.<br>1: A transfer error (TE) occurred on channel 1.    |
| 8   | GIF2       | 0x0   | R  | Channel 2 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 2.<br>1: A TE, HT or TC event occurred on channel 2.          |
| 9   | TCIF2      | 0x0   | R  | Channel 2 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 2.<br>1: A transfer complete (TC) occurred on channel 2. |

| Bit | Field name | Reset | RW | Description                                                                                                                                                                                                                                           |
|-----|------------|-------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | HTIF2      | 0x0   | R  | Channel 2 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 2.<br>1: A half transfer (HT) event occurred on channel 2. |
| 11  | TEIF2      | 0x0   | R  | Channel 2 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 2.<br>1: A transfer error (TE) occurred on channel 2.    |
| 12  | GIF3       | 0x0   | R  | Channel 3 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 3.<br>1: A TE, HT or TC event occurred on channel 3.          |
| 13  | TCIF3      | 0x0   | R  | Channel 3 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 3.<br>1: A transfer complete (TC) occurred on channel 3. |
| 14  | HTIF3      | 0x0   | R  | Channel 3 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 3.<br>1: A half transfer (HT) event occurred on channel 3. |
| 15  | TEIF3      | 0x0   | R  | Channel 3 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 3.<br>1: A transfer error (TE) occurred on channel 3.    |
| 16  | GIF4       | 0x0   | R  | Channel 4 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 4.<br>1: A TE, HT or TC event occurred on channel 4.          |
| 17  | TCIF4      | 0x0   | R  | Channel 4 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 4.<br>1: A transfer complete (TC) occurred on channel 4. |
| 18  | HTIF4      | 0x0   | R  | Channel 4 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 4.<br>1: A half transfer (HT) event occurred on channel 4. |

| Bit | Field name | Reset | RW | Description                                                                                                                                                                                                                                           |
|-----|------------|-------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19  | TEIF4      | 0x0   | R  | Channel 4 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 4.<br>1: A transfer error (TE) occurred on channel 4.    |
| 20  | GIF5       | 0x0   | R  | Channel 5 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 5.<br>1: A TE, HT or TC event occurred on channel 5.          |
| 21  | TCIF5      | 0x0   | R  | Channel 5 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 5.<br>1: A transfer complete (TC) occurred on channel 5. |
| 22  | HTIF5      | 0x0   | R  | Channel 5 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 5.<br>1: A half transfer (HT) event occurred on channel 5. |
| 23  | TEIF5      | 0x0   | R  | Channel 5 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 5.<br>1: A transfer error (TE) occurred on channel 5.    |
| 24  | GIF6       | 0x0   | R  | Channel 6 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 6.<br>1: A TE, HT or TC event occurred on channel 6.          |
| 25  | TCIF6      | 0x0   | R  | Channel 6 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 6.<br>1: A transfer complete (TC) occurred on channel 6. |
| 26  | HTIF6      | 0x0   | R  | Channel 6 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 6.<br>1: A half transfer (HT) event occurred on channel 6. |
| 27  | TEIF6      | 0x0   | R  | Channel 6 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 6.<br>1: A transfer error (TE) occurred on channel 6.    |

| Bit | Field name | Reset | RW | Description                                                                                                                                                                                                                                           |
|-----|------------|-------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28  | GIF7       | 0x0   | R  | Channel 7 global interrupt flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No TE, HT or TC event on channel 7.<br>1: A TE, HT or TC event occurred on channel 7.          |
| 29  | TCIF7      | 0x0   | R  | Channel 7 transfer complete flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer complete (TC) on channel 7.<br>1: A transfer complete (TC) occurred on channel 7. |
| 30  | HTIF7      | 0x0   | R  | Channel 7 half transfer flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No half transfer (HT) event on channel 7.<br>1: A half transfer (HT) event occurred on channel 7. |
| 31  | TEIF7      | 0x0   | R  | Channel 7 transfer error flag. This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the IFCR register.<br>0: No transfer error (TE) event on channel 7.<br>1: A transfer error (TE) occurred on channel 7.    |

Table 39: DMA - IFCR register description: address offset DMA\_BASE\_ADDR+0x04

| Bit | Field name | Reset | RW | Description                                                                                                                                         |
|-----|------------|-------|----|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | CGIF0      | 0x0   | W  | Channel 0 global interrupt flag. This bit is set by software.<br>0: No effect.<br>1: Clears the GIF, TEIF, HTIF and TCIF flags in the ISR register. |
| 1   | CTCIF0     | 0x0   | W  | Channel 0 transfer complete flag. This bit is set by software.<br>0: No effect.<br>1: Clears the corresponding TCIF flag in the ISR register.       |
| 2   | CHTIF0     | 0x0   | W  | Channel 0 half transfer flag. This bit is set by software.<br>0: No effect.<br>1: Clears the corresponding HTIF flag in the ISR register.           |
| 3   | CTEIF0     | 0x0   | W  | Channel 0 transfer error flag. This bit is set by software.<br>0: No effect.<br>1: Clears the corresponding TEIF flag in the ISR register.          |
| 4   | CGIF1      | 0x0   | W  | Channel 1 global interrupt flag. This bit is set by software.<br>0: No effect.<br>1: Clears the GIF, TEIF, HTIF and TCIF flags in the ISR register. |

| Bit | Field name | Reset | RW | Description                                                                                                                                         |

Access is automatically aligned to a halfword address. When MSIZE is 10 (32-bit), MA[1:0] are ignored. Access is automatically aligned to a word address. |

All RESERVED fields inside registers must always be written with their default values.

## 3.8 SPI

### 3.8.1 Introduction

The BlueNRG-1 integrates a serial peripheral interface compatible with the Motorola and National Semiconductor Microwire standards.

Main features are:

- Maximal supported baud rate is 1 MHz in slave mode and 8 MHz in master mode.
- Parallel-to-serial conversion on data written to an internal 32-bit wide, 16-location deep transmitter FIFO.
- Serial-to-parallel conversion on received data, buffering in a 32-bit wide 16-location deep receive FIFO.
- Programmable data frame size from 4-bit to 32-bit.
- Programmable clock bit rate and prescaler.
- Programmable clock phase and polarity in SPI mode.
- Support for direct memory access (DMA).

### 3.8.2 Functional overview

The SPI performs serial-to-parallel conversion on data received from a peripheral device on the SPI\_IN pin, and parallel-to-serial conversion on data written by CPU for transmission on the SPI\_OUT pin.

The role of the SPI pins are defined by the SPI master or SPI slave role.

**Table 45: SPI pin assignments**

| SPI role | SPI_IN pin | SPI_OUT pin |
|----------|------------|-------------|
| Master   | MISO       | MOSI        |
| Slave    | MOSI       | MISO        |

The transmit and receive paths are buffered with internal FIFO memories allowing up to 16 x 32-bit values to be stored independently in both transmit and receive modes. FIFOs may be burst-loaded or emptied by the system processor or by the DMA, from one to eight words per transfer. Each 32-bit word from the system fills one entry in FIFO.

The SPI includes a programmable bitrate clock divider and prescaler to generate the serial output clock signal from the SPI\_CLK pin.

### 3.8.2.1 SPI clock phase and clock polarity

The SPH control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. The SPO bit selects the clock polarity (low or high) of the clock signal. SPH in conjunction with the SPO bit allow four possible timing variations listed in the following table.

**Table 46: SPI clock phase and clock polarity**

| SPH | SPO | Timing description                                                                                                                                                                                                                                                                                                                                                                                |
|-----|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b  | 0b  | The clock signal is stopped to low inactive level between transfers. The first rising edge occurs in the middle of the first data bit (with delay). The SPI transmits data one-half cycle ahead of the rising edge of clock signal and receives data on the rising edge of clock signal. In case of multi byte transmission, the CS line must be pulsed HIGH between each data word transfer.     |
| 0b  | 1b  | The clock signal is stopped to high inactive level between transfers. The first falling edge occurs in the middle of the first data bit (with delay). The SPI transmits data one-half cycle ahead of the falling edge of clock signal and receives data on the falling edge of clock signal. In case of multi byte transmission, the CS line must be pulsed HIGH between each data word transfer. |
| 1b  | 0b  | The clock signal is stopped to low inactive level between transfers. The first rising edge occurs at the start of the first data bit (no delay). The SPI transmits data on the rising edge of clock signal and receives data on the falling edge of clock signal.                                                                                                                                 |
| 1b  | 1b  | The clock signal is stopped to high inactive level between transfers. The first falling edge occurs at the start of the first data bit (no delay). The SPI transmits data on the falling edge of clock signal and receives data on the rising edge of clock signal.                                                                                                                               |

### 3.8.2.2 Procedure for enabling SPI

The SPI initialization procedure is the following (assuming clocks already enabled):

1. Clear the SSE bit in the CR1 register. This step is not required after a hardware or software reset of the BlueNRG1.
2. Empty the receive FIFO. This step is not required after a hardware or software reset of the device BlueNRG1.
3. Program IO\_MODE to route SPI port signals on those GPIOs. See section GPIO operating modes.
4. Program the SPI clock prescaler register (CPSR), then program the configuration registers CR0 and CR1.
5. The transmit FIFO can optionally be filled before enabling the SPI.
6. Set the SSE bit to enable SPI operation.

The transmit FIFO and the receive FIFO are not cleared when the SSE bit is cleared.

### 3.8.2.3 SPI bit rate generation

The SPI bitrate is derived by dividing down the peripheral clock (CLK) by an even prescaler value CPSDVSR from 2 to 254, the clock is further divided by a value from 1 to 256, which is  $1+SCR$ . The SPI frequency clock duty cycle is always 0.5.

### 3.8.2.4 SPI data endianness

All transfers can be sent and received with configurable endianness according the setting of the (T/R)ENDN bit in the CR1 registers

The cases "00b" and "11b" of TENDN and RENDN are implemented for data frame size from 4- to 32-bit. The cases "01b" and "10b" of TENDN and RENDN are implemented only for the following data frame sizes: 16-bit, 24-bit and 32-bit. Transmit data endianness: TENDN in CR1:

**Table 47: SPI\_OUT endianness**

| TENDN | Endianness                                               |
|-------|----------------------------------------------------------|
| 00b   | The element is transmitted MSByte-first and MSbit-first. |
| 01b   | The element is transmitted LSByte-first and MSbit-first. |
| 10b   | The element is transmitted MSByte-first and LSbit-first. |
| 11b   | The element is transmitted LSByte-first and LSbit-first. |

**Table 48: SPI\_IN endianness**

| RENDN | Endianness                                            |
|-------|-------------------------------------------------------|
| 00b   | The element is received MSByte-first and MSbit-first. |
| 01b   | The element is received LSByte-first and MSbit-first. |
| 10b   | The element is received MSByte-first and LSbit-first. |
| 11b   | The element is received LSByte-first and LSbit-first. |

### 3.8.2.5 SPI interrupts

There are six individual maskable interrupt sources generated by the SPI (single interrupt signal that drives the NVIC):

- Receive interrupt
- Transmit interrupt
- Timeout interrupt
- Receive overrun interrupt
- Transmit underrun interrupt
- Transmit empty interrupt

The user can enable or disable the individual interrupt sources by changing the mask bits in the IMSC register. Setting the appropriate mask bit to 1b enables the interrupt. The status of the individual interrupt sources can be read from the RIS register (raw interrupt status) or from the MIS register (masked interrupt status).

### 3.8.2.6 Receive interrupt

The receive interrupt is asserted when the number of data in receive FIFO reaches the programmed trigger watermark level. The receive interrupt is cleared by reading data from the receive FIFO until there are less data than the programmed watermark level.

### 3.8.2.7 Transmit interrupt

The transmit interrupt is asserted when the number of data in the transmit FIFO is less than or equal to the programmed watermark level. It is cleared by performing writes to the transmit FIFO until it holds more elements than the programmed watermark level. The

transmitter interrupt is not qualified with the SPI enable bit, which allows operation in one of two ways:

- Data can be written to the transmit FIFO prior to enabling the SPI and the interrupts.
- Or the SPI and the interrupts can be enabled so that data can be written to the transmit FIFO by an interrupt service routine.

### 3.8.2.8 Timeout interrupt

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period of the serial clock. This mechanism ensures that the user is aware that data is still present in the receive FIFO and requires servicing.

The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data, or if new data is received, or when a 1b is written to the corresponding bit of the ICR register.

### 3.8.2.9 Receive overrun interrupt

Receive overrun interrupt is asserted when the receive FIFO is already full and an additional data frame is received, causing an overrun of the FIFO. Data is overwritten in the receive shift register, but not in the FIFO. The interrupt is cleared when a 1b is written to the corresponding bit of the ICR register.

### 3.8.2.10 Transmit underrun interrupt

The transmit underrun interrupt is asserted when the transmit FIFO is already empty and an additional frame is transmitted, causing an underrun of the FIFO. Data is over-read in the transmit shift register. This interrupt is cleared when a 1b is written to the corresponding bit of the ICR register.

### 3.8.2.11 Transmit empty interrupt

The transmit interrupt is asserted when the transmit FIFO is empty. It is cleared by performing writes to the transmit FIFO.

### 3.8.2.12 SPI master communication mode for Motorola standard

The SPIM register field selects the SPI transmission mode, these modes are applicable only for SPI master mode:

- Full duplex mode (SPIM = 00b): the master transmits the data available in the TXFIFO and receives the data from the slave.
- Transmit mode (SPIM = 01b): when the data is available in TX FIFO, the SPI\_OUT line is run, and no data is written in RX FIFO
- Receive mode (SPIM = 10b): the sequence of receive mode is: When the receive mode is selected we have two cases:
  - a. The software sets the mode to receive (SPIM = 10) and writes the dummy character value to the CHN register.
  - b. The software writes the value "number of frames to receive from the slave" in the RXFRM register.
    - a. If the TXFIFO is empty, the master receives data from the slave, transmitting the character from the CHN register in each frame received. The RXFRM register is decremented by one at each transmission/reception. The interface runs until the RXFRM value is dummy AND the written number of frames in RXFRM is received.
    - b. If the TXFIFO is not empty, the master first transmits the data available in the TXFIFO and receives the data from the slave (like the full duplex mode). The RXFRM register is not decremented. When all the data available in TXFIFO are

transmitted, the TXFIFO becomes empty (case a), then the dummy character from the CHN register are transmitted for each frame received. The RXFRM register is decremented for each transaction. When the value in this register is zero and the written number of frames in RXFRM is received, the interface does not run anymore. The user has to write the RXFRM (with value greater than zero) by software to reactivate the interface.

In all cases, the RXFRM is decremented by one only if the TXFIFO is empty. The RFRM is decremented before the data is sent.

If the software fills the TXFIFO while the SPI is transmitting the dummy character, then the words of TXFIFO should be ignored and we should not send them in this mode, only the dummy -character are transmitted.

- Combined mode (SPIM = 11b): the sequence of combined mode is:
  - a. The software sets the mode to combined mode: (SPIM=11).
  - b. The software writes to the WDTXF register the "number of frames to be received by the slave (a value greater than zero) from TXFIFO master".

If the number of words written in the WDTXF register are sent (WDTXF is equal to zero) but the RXFRM register is not equal to zero, the master transmits the dummy character (defined in CHM register) and receives the slave data, decrementing the RXFRM register by one. Once the RXFRM register is equal to zero and all the data written in RXFRM are sent, the interface is stopped.

When the RXFRM register is zero and WDTXF is not equal to zero and the TXFIFO of the master and of slave are not empty, the master transmits the data from TXFIFO and receives the data from the slave. Before the data is sent from TXFIFO, the WDTXF is decremented by one. When the WDTXF register is zero and all the numbers written in this register are sent, the interface is stopped.

The interface is stopped when:

- WDTXF and RXFRM registers are equal to zero.
- WDTXF register is not equal to zero and TXFIFO is empty.
- RXFRM register is not equal to zero, the WDTXF register is zero and TXFIFO is not empty.

For each data transmission (TXFIFO data or CHN register data), the data slave is received.

WDTXF is decremented by one only at each data transmission from TXFIFO. The decrementing is done before the words are sent out.

RXFRM is decremented by one only at each dummy character transmission from the CHN register. The decrementing is done before the words are sent out.

When we start decrementing one of the registers (RXFRM or WDTXF), we must decrement until we reach zero and we send the last words before starting the decrement of other registers (RXFRM or WDTXF).

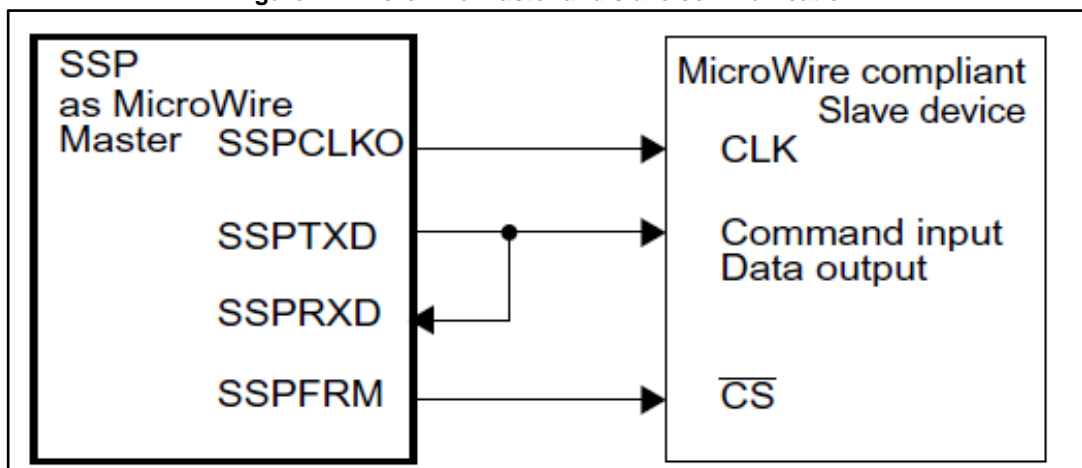

Switching between these different modes when SPI is enabled is possible. If the transmission mode is deselected for another mode during a frame transmission, the new mode becomes active at the start of the next word.

### 3.8.2.13 SPI master communication mode for National Semiconductor Microwire standard

The FRF register field selects the SPI mode interface: the default value 0 indicates the Motorola standard interface, while FRF = 2 selects the Microwire standard interface for the 3-wire SPI mode.

The hardware connection considers the SPI\_IN and SPI\_OUT pins connected together as shown in the figure below. The two pins are handled internally to send and receive data.

Figure 12: MicroWire master and slave communication

The CSS register field specifies the length of the data to send and the DSS register field specifies the length of the data to receive.

In reception mode, the quantity of data to read is specified in the DSS register field. The set of the SSE register field, enables SPI for the communication. The user should wait for data reception to end before attempting any reads. The SSE register field must be reset at the end of the communication.

In transmission mode, the send data are written inside the TX FIFO and the quantity of data to send is specified in the CSS register field. The SSE register field setting enables SPI for the communication. When the busy flag is RESET, SPI communication is terminated. The SSE register field must be reset at the end of the communication.

### 3.8.3 SPI registers

SPI peripheral base address (SPI\_BASE\_ADDR) 0x40400000.

Table 49: SPI registers

| Address offset | Name | RW | Reset      | Description                                                       |

## 3.9 UART

### 3.9.1 Introduction

The BlueNRG-1 integrates a universal asynchronous receiver/transmitter that support much of the functionality of the industry-standard 16C650 UART.

Main features are:

- Programmable baud rates up to 2 Mbps.
- Programmable data frame of 5, 6, 7 or 8 bits of data.
- Even, odd, stick or no-parity bit generation and detection.
- Programmable 1 or 2 stop bit.
- Support of hardware flow control using CTS and RTS pins.
- Support of software flow control using programmable Xon/Xoff characters
- False start bit detection.
- Line break generation and detection.

- Programmable 8-bit wide, 64-deep transmit FIFO and 12-bit wide (8-bit data and 4-bit status) , 64-deep receive FIFO.
- Support for direct memory access (DMA).

### 3.9.2 Functional description

The UART performs serial-to-parallel conversion on data asynchronously received from a peripheral device on the UART\_RX pin, and parallel-to-serial conversion on data written by CPU for transmission on the UART\_TX pin. The transmit and receive paths are buffered with internal FIFO memories allowing up to 64 data byte for transmission, and 64 data byte with 4-bit status (break, frame, parity, and overrun) for receive. FIFOs may be burst-loaded or emptied by the system processor from 1 to 16 words per transfer.

#### 3.9.2.1 Data transmission or reception

Data received or transmitted is stored in two 64-byte FIFOs. The receive FIFO has an extra four bits per character for the status information:

- Error bits 8 to 10 are associated with a particular character: break error, parity error and framing error.
- Overrun indicator bit 11 is set when the FIFO is full, and the next character is completely received in the shift register. The data in the shift register is overwritten, but it is not written into the FIFO. When an empty location is available in the receive FIFO, and another character is received, the state of the overrun bit is copied into the received FIFO along with the received character. The overrun state is then cleared.

Table 65: RX FIFO errors

| FIFO bit | Function          |
|----------|-------------------|
| 11       | Overrun indicator |
| 10       | Break error       |
| 9        | Parity error      |
| 8        | Framing error     |
| 7:0      | Received data     |

For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in LCRH\_TX. Data continue to be transmitted until there is no data left in the transmit FIFO. The BUSY flag in the UARTFR register is set as soon as data is written to the transmit FIFO (that is, the FIFO is non-empty) and remains asserted while data is being transmitted. BUSY is cleared only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. BUSY can be set even though the UART might no longer be enabled. For each sample of data, three readings are taken and the majority value is kept. In the following paragraphs, the middle sampling point is defined, and one sample is taken either side of it. When the receiver detect a start bit, the receive counter runs and data is sampled on the 8th cycle of that counter in normal UART mode. The start bit is valid if UART\_RX signal is still low on the eighth cycle of Baud16, otherwise a false start bit is detected and it is ignored. If the start bit is valid, successive data bits are sampled on every 16th cycle of Baud16 (that is 1-bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled. Lastly, a valid stop bit is confirmed if UART\_RX signal is high, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that. The UART character frame is shown in [Figure 13: "UART character frame"](#) below.

Figure 13: UART character frame

The FIFOs can be disabled. In this case, the transmit and receive sides of the UART have 1-byte holding registers (the bottom entry of the FIFOs). The overrun bit is set when a word has been received, and the previous one was not yet read. In this implementation, the FIFOs are not physically disabled, but the flags are manipulated to give the illusion of a 1-byte register.

### 3.9.2.2 Baud rate divisor

The baud rate divisor is a 22-bit number consisting of a 16-bit integer (BRDI) and a 6-bit fractional part (BRDF). The fractional baud rate divisor enables the use of any clock to act as UART\_CLK, while it is still possible to generate all the standard baud rates.

The 16-bit integer is loaded through the UART\_IBRD register and the 6-bit fractional part is loaded into the UART\_FBRD register. The baud rate divisor has the following relationship:

When bit OVSFAC = 0b: divisor =  $\text{UARTCLK} / (16 \times \text{baud rate}) = \text{BRDI} + \text{BRDF}$ .

When bit OVSFAC = 1b: divisor =  $\text{UARTCLK} / (8 \times \text{baud rate}) = \text{BRDI} + \text{BRDF}$ .

Calculation of the fractional 6-bit number (DIVFRAC) is done by taking the fractional part of the required baud rate divisor and multiplying it by 64 (that is,  $2^n$ , where  $n$  is the width of the UART\_FBRD register) and adding 0.5 to account for rounding errors:

$$\text{DIVFRAC} = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The maximum deviation error using a 6-bit UART\_FBRD register is  $1/64 * 100 = 1.56\%$ .

This occurs when DIVFRAC = 1, and the error is cumulative over 64 clock ticks.

**Example 1:** Calculating the divisor value (with OVSFAC = 0b).

If the required baud rate is 460 800 and the UART clock frequency is 16 MHz then:

$$\text{Baud rate divisor} = (16 \times 10^6) / (16 \times 460\,800) = 2.170$$

$$\text{BRDI} = 2 \text{ and } \text{BRDF} = 0.170$$

$$\text{Therefore fractional part DIVFRAC} = \text{integer}(\text{BRDF} * 64 + 0.5) = 11$$

$$\text{Generated baud rate divider} = 2 + (11 / 64) = 2.1718$$

$$\text{Generated baud rate} = (16 \times 10^6) / (16 \times 2.172) = 460\,447$$

$$\text{Error} = (460\,800 - 460\,405) / 460\,800 \times 100 = 0.077\%$$

An internal clock enable signal, BaudI6, is generated, and is a stream of one UARTCLK wide pulses with an average frequency of 16 (OVSFAC = 0b) or 8 (OVSFAC = 1b) times the desired baud rate. This signal is then divided by 16 or 8 to give the transmit clock. A low number in the baud rate divisor gives a short bit period, and a high number in the baud rate divisor gives a long bit period.

*Table 66: "Typical baud rates with OVSFAC = 0"* shows some typical bit rates and their corresponding divisors when OVSFAC = 0b, given the UART clock frequency of 16 MHz.

**Table 66: Typical baud rates with OVSFAC = 0**

### 3.9.2.3 Hardware flow control

The hardware flow controls feature is fully selectable through RTSEN and CTSEN in UARTCR register, and allows to control the serial data flow by using the UART\_RTS output and UART\_CTS input signals.

Figure 14: Hardware flow control between two similar devices

When the RTS flow control is enabled, the UART\_RTS signal is asserted until the receive FIFO is filled up to the programmed watermark level. When the CTS flow control is enabled, the transmitter can only transmit data when the UART\_CTS signal is asserted.

Table 68: Control bits to enable and disable hardware flow control

| CTSEN | RTSEN | Function                                |
|-------|-------|-----------------------------------------|
| 0b    | 0b    | Both RTS and CTS flow control disabled. |
| 0b    | 1b    | Only RTS flow control enabled.          |
| 1b    | 0b    | Only CTS flow control enabled.          |
| 1b    | 1b    | Both RTS and CTS flow control enabled.  |

The RTS flow control logic is linked to the programmable receive FIFO watermark levels. When RTS flow control is enabled, the UART\_RTS is asserted until the receive FIFO is

filled up to the watermark level. When the receive FIFO watermark level is reached, the UART\_RTS signal is de-asserted, indicating that there is no more room to receive any more data. The transmission of data is expected to cease after the current character has been transmitted. The UART\_RTS signal is reasserted when data has been read out of the receive FIFO so that it is filled to less than the watermark level. If RTS flow control is disabled and the UART is still enabled, then data is received until the receive FIFO is full, or no more data is transmitted to it.

If CTS flow control is enabled, then the transmitter checks the UART\_CTS signal before transmitting the next byte. If the UART\_CTS signal is asserted, it transmits the byte otherwise, transmission does not occur. The data continues to be transmitted while UART\_CTS is asserted, and the transmit FIFO is not empty. If the transmit FIFO is empty and the UART\_CTS signal is asserted no data is transmitted. If the UART\_CTS signal is de-asserted and CTS flow control is enabled, then the current character transmission is completed before stopping. If CTS flow control is disabled and the UART is enabled, then the data continues to be transmitted until the transmit FIFO is empty.

### 3.9.2.4 Software flow control

Software flow control is enabled through register UART\_XFCR bit SFEN.

#### Software receive flow control

Once the software receive flow control is enabled, the receiver compares the incoming data with the programmed Xoff values. Different combinations of software receive flow control, which can be selected through SFRMOD, where only 1 character match is needed or in which 2 Xoff characters must be received sequentially.

**Table 69: Control bits to enable and program receive software flow control**

| SFSEN | SFRMOD | Function                                     |
|-------|--------|----------------------------------------------|
| 0b    | xxb    | Software flow control disabled.              |
| 1b    | 00b    | Software receive flow control disabled.      |
| 1b    | 01b    | Use Xon1, Xoff1 for matching.                |
| 1b    | 10b    | Use Xon2, Xoff2 for matching.                |
| 1b    | 11b    | Use Xon1 & Xon2, Xoff1 & Xoff2 for matching. |

If received characters match the programmed Xoff values, the transmission stops as soon as the current character is completely transferred. The interrupt bit XOFRIS in the raw interrupt register UART\_RIS is set. If the corresponding interrupt mask bit is set, the corresponding bit in the UART\_MIS register is set and the UART interrupt pin is asserted. Following such a transmission suspension, the receiver will monitor incoming characters for a match with the programmed Xon values. The matching strategy is programmable through SWRFCPROG in register UART\_XFCR. Once a match is found, the receiver clears the interrupt bit XOFRIS in the raw interrupt register UART\_RIS and the Xoff interrupt is disabled. The transmission can then resume normally. When the XONANY bit in register UART\_XFCR is set, any incoming character is accepted as a valid Xon condition and the transmission can then resume. The received character is written into the received FIFO.

If the software flow control is enabled, the received Xon/Xoff characters are never written into the received FIFO. Exceptions to this occur when the special character detection feature is enabled (Xoff2 is then written into FIFO upon a special character match) and when the Xon-any bit is set.

The received status (parity, framing and break error) of Xon/Xoff characters does not have to be valid for these characters to be accepted as valid matches.

When the software transmit flow control is enabled through the SFTMOD bit field in the UART\_XFCR register, the transmitter will automatically insert an Xoff character if the received FIFO has passed the received trigger level (bit field RXIFLSEL in the UART\_IFLS register). The RTXDIS (remote transmitter disabled) bit in the UART\_FR register is set to signal the remote transfer was stopped. When the receive FIFO falls below the trigger level, Xon character is automatically inserted in the transmission stream and the RTXDIS bit in the UART\_FR register is cleared.

**Table 70: Control bits to enable and program transmit software flow control**

| SFSEN | SFTMOD | Function                                         |
|-------|--------|--------------------------------------------------|
| 0b    | xxb    | Software flow control disabled.                  |
| 1b    | 00b    | Software transmit flow control disabled.         |
| 1b    | 01b    | Use Xon1, Xoff1 for matching.                    |
| 1b    | 10b    | Use Xon2, Xoff2 for matching.                    |
| 1b    | 11b    | Use Xon1 and Xon2, Xoff1 and Xoff2 for matching. |

After Xoff character has been transmitted, if the software flow controlled is turned off, a Xon character is automatically be inserted in the transmission stream and the bit RTXDIS bit in the UART\_FR register is cleared.

Transmission of Xon/Xoff character follows the standard transmission protocol as programmed in the transmitter registers (word length, parity and so on).

When using the software transmit flow control, there are some cautions to take to manage the interrupt handler. The software must react on RX interrupt (the flag is raised once the RX FIFO contains the RXIFSEL trigger level. Then the interrupt handler must first poll the UART\_FR.RTXDIS bit until it is set to indicate the Xoff byte transmission is over and only then read the RX FIFO content. Note that hardware and software flow control cannot be enabled simultaneously.

### Software transmit flow control

When the special character detection feature is enabled through the SPECHAR bit in the UART\_XFCR register, the software flow control is turned off and the receiver compares received characters with the Xoff2 value. When a match is found, the interrupt bit XOFFRIS in the raw interrupt register UART\_RIS is set. If the corresponding interrupt mask bit is set, the UART interrupt pin is asserted. The transmission is not halted. The special character is written into the received FIFO. The interrupt bit XOFFIS will be cleared when the corresponding bit in interrupt clear register is written as 1b.

It is assumed that software flow control is turned off when this feature is used. The received status (i.e. parity, framing and break error) of special characters does not have to be valid for these characters to be accepted as valid matches.

### 3.9.2.5 UART interrupts

There are six individual maskable interrupt sources generated by the UART (single interrupt signal that drives the NVIC):

- TX FIFO empty interrupt
- Xoff/ special character interrupt
- Receive interrupt
- Transmit interrupt
- Timeout interrupt
- Error interrupt

The user can enable or disable the individual interrupt sources by changing the mask bits in the UART\_IMSC register. Setting the appropriate mask bit to 1b enables the interrupt. The status of the individual interrupt sources can be read from the UART\_RIS register (raw interrupt status) or from the UART\_MIS register (masked interrupt status).

### 3.9.2.6 TX FIFO empty interrupt

The TX FIFO empty interrupt is asserted whenever the BUSY status bit goes low to indicate that all DATA has been transmitted. This BUSY bit remains set until the complete byte, including all the stop bits, has been sent from the shift register. So, the new TX FIFO empty interrupt is asserted when the transmit FIFO and the transmit shift register are empty.

### 3.9.2.7 Xoff/ special character interrupt

The Xoff/special character interrupt is asserted whenever Xoff condition is detected by the receiver (incoming data matches with the programmable Xoff values), or when a special character detection was performed (incoming data matches with the Xoff2 and SPECHAR bit set).

### 3.9.2.8 Receive interrupt

The receive interrupt is asserted HIGH when one of the following conditions occurs:

- If the FIFOs are enabled and the number of characters received reaches the programmed trigger watermark level. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the programmed watermark level, or by clearing the interrupt by writing a 1b to the corresponding bit in the UART\_ICR register.
- If the FIFOs are disabled (have a depth of one location) and there is a data present in the receiver single location. It is cleared by performing a single read.

### 3.9.2.9 Transmit interrupt

The transmit interrupt is asserted HIGH when one of the following conditions occurs:

- If the FIFOs are enabled and the number of characters in the transmit FIFO is less than the programmed watermark level. It is cleared by performing writes to the transmit FIFO until it holds more characters than the programmed watermark level, or by clearing the interrupt by software.

- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitter single location. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by software.

The transmit FIFO service interrupt is based on a transition through a level, rather than on the level itself. When the interrupt and the UART are enabled before any data is written to the transmit FIFO, the interrupt is not set. The interrupt is only set once written data leaves the single location of the transmit FIFO and it becomes empty.

When the TX FIFO is disabled, the DATA can be written on the bottom of the FIFO during the transmission of a previous DATA, or in another words, when the holding register is busy.

The interrupt is de-asserted when we write the next DATA on the bottom of the TX FIFO. If we write DATA only on the holding register and the bottom of the TX FIFO is empty, the only way to clear the interrupt is by the software.

#### 3.9.2.10 Timeout interrupt

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received (or no correct start bit of a frame is detected in the RX line) over a programmable timeout period. This mechanism ensures that the user is aware that data is still present in the receive FIFO and requires servicing. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1b is written to the corresponding bit of the UART\_ICR register.

#### 3.9.2.11 Error interrupt

The error interrupt is asserted when an error occurs in the reception of data by the UART. The interrupt can be caused by the following error conditions:

- Framing
- Parity
- Break
- Overrun

The cause of the interrupt is available by reading the UART\_RIS or UART\_MIS registers. The interrupt can be cleared by writing to the relevant bits of the UART\_ICR register.

### 3.9.3 UART registers

UART peripheral base address (UART\_BASE\_ADDR) 0x40300000.

Table 71: UART registers

| Address offset | Name    | RW | Reset      | Description                                                                                                               |
|----------------|---------|----|------------|---------------------------------------------------------------------------------------------------------------------------|
| 0x00           | DR      | RW | 0x00000000 | Data register. Refer to the detailed description below.                                                                   |
| 0x04           | RSR     | R  | 0x00000000 | Receive status register. Refer to the detailed description below.                                                         |
| 0x04           | ECR     | W  | 0x00000000 | Error clear register. A write to this register clears the framing (FE), parity (PE), break (BE), and overrun (OE) errors. |
| 0x0C           | TIMEOUT | RW | 0x000001FF | Timeout register. Refer to the detailed description below.                                                                |
| 0x18           | FR      | R  | 0x00001E90 | Flag register. Refer to the detailed description below.                                                                   |

Table 72: UART - DR register description: address offset UART\_BASE\_ADDR+0x00

| Bit   | Field name | Reset | RW | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|------------|-------|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0   | DATA       | 0x0   | RW | UART data register:<br>Receive: read data character.<br>Transmit: write data character.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8     | FE         | 0x0   | R  | Frame error. This bit is set to 1 if the received character did not have a valid stop bit. In FIFO mode, this error is associated with the character at the top of the FIFO.                                                                                                                                                                                                                                                                                                                                        |
| 9     | PE         | 0x0   | R  | Parity error. This bit is set to 1 if the parity of the received data character does not match the parity selected as defined by bits 2 and 7 of the LCRH_RX register. In FIFO mode, this error is associated with the character at the top of the FIFO.                                                                                                                                                                                                                                                            |
| 10    | BE         | 0x0   | R  | Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held low for longer than a full-word transmission time (defined as start, data, parity and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to HIGH (marking state), and the next valid start bit is received |
| 11    | OE         | 0x0   | R  | Overrun error. This bit is set to 1 if data is received and the receive FIFO is already full. This is cleared to 0b once there is an empty space in the FIFO and a new character can be written to it. The FIFO content remains valid since no further data is written when the FIFO is full, only the content of the shift register is overwritten.                                                                                                                                                                |
| 31:12 | RESERVED   | 0x0   | R  | RESERVED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

In FIFO mode, this error is associated with the character at the top of the FIFO.                                                     |
| 1   | PE         | 0x0   | R  | Parity error. This bit is set to 1 if the parity of the received data character does not match the parity selected as defined by bits 2 and 7 of the LCRH_RX register. This bit is cleared to 0b after a write to ECR. In FIFO mode, this error is associated with the character at the top of the FIFO. |

| Bit  | Field name | Reset | RW | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|------------|-------|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2    | BE         | 0x0   | R  | Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held low for longer than a full-word transmission time (defined as start, data, parity and stop bits). This bit is cleared to 0b after a write to ECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to HIGH (marking state), and the next valid start bit is received. |
| 3    | OE         | 0x0   | R  | Overrun error. This bit is set to 1 if data is received and the receive FIFO is already full. This is cleared to 0 by a write to ECR (data value is not important). The FIFO contents remain valid since no further data is written when the FIFO is full, only the content of the shift register are overwritten. The CPU or DMA must now read the data in order to empty the FIFO.                                                                                                                                                                                 |
| 31:4 | RESERVED   | 0x0   | R  | RESERVED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 3   | BUSY       | 0x0   | R  | UART Busy. If this bit is set to 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all the stop bits, has been sent from the shift register. However, if the transmit section of the UART is disabled in the middle of a transmission, the BUSY bit gets cleared. This bit is set again once the transmit section is re-enabled to complete the remaining transmission. This bit is set as soon as the transmit FIFO becomes nonempty (regardless of whether the UART is enabled or not). |
| 4   | RXFE       | 0x1   | R  | Receive FIFO empty. If the FIFO is disabled (bit FEN = 0b), this bit is set when the receive holding register is empty. If the FIFO is enabled (FEN = 1b), the RXFE bit is set when the receive FIFO is empty.                                                                                                                                                                                                                                                                                                                         |

| 19:16 | STA_B_DURATION | 0x4   | RW | START bit duration receiver state. These bits can be used to configure the START bit duration (in clock cycles) to get the bit sampled in the middle of the UART receiver. These bits can be used only when using high baud rates (IBRD = 1, FBRD ≥ 0 and OVSFACT = 1). Below the formula to calculate the START bit duration receiver state:<br>$STA\_B\_DURATION = \text{Integer}(\text{Fuartclk}/(2 * \text{BAUD RATE})) - 1$<br>Example: when UARTCLK = 16 MHz and BAUD RATE = 2.0 Mbps then $STA\_B\_DURATION = 4 - 1 = 3$ . STA_B_DURATION field should be configured with 4'b0011. |

All RESERVED fields inside registers must always be written with their default values.

## 3.10 I<sup>2</sup>C

### 3.10.1 Introduction

The BlueNRG-1 integrates two I<sup>2</sup>C controllers in the QFN32 package (I2C2 and I2C1), and one in the WCSP34 package (I2C2). The I<sup>2</sup>C controller interface is designed to support the physical and data link layer according to I<sup>2</sup>C standard revision 3.0 and provides a low-cost interconnection between ICs.

Main features are:

- Up to 400 Kb/s in fast mode and up to 100 Kb/s in standard mode.
- Operating modes supported are master mode, slave mode, master/slave mode for multi-master system with bus arbitration.
- Programmable 7-bit or 10-bit addressing (also with combined formats).
- Programmable start byte procedure.
- 16-byte depth RX FIFO and 16-byte depth TX FIFO.
- Spike digital filtering on the SDA and SCL lines.
- Control timing constraint defined by the I<sup>2</sup>C standard.
- Support for direct memory access (DMA).

### 3.10.2 Functional description

Two wires, serial data (SDA) and serial clock (SCL) carry information between the devices connected to the bus. Each device has a unique address and can operate as either a transmitter or receiver, depending on the function of the device. A master is the device that initiates a data transfer on the bus and generates the clock signal. Any device addressed is considered at that time a slave. The I<sup>2</sup>C bus is a multi-master bus where more than one device is capable of controlling the bus. This means that more than one master could try to initiate a data transfer at the same time. The arbitration procedure relies on the wired-AND connection of all I<sup>2</sup>C interfaces to the I<sup>2</sup>C bus. If two or more masters try to put information onto the bus, the first to produce a 'one' when the other produces a 'zero' will lose the arbitration. The clock signals during arbitration are a synchronized combination of the clocks generated by the masters using the wired-AND connection to the SCL line. Generation of clock signals on the I<sup>2</sup>C bus is always the responsibility of master devices; each master generates its own clock signals when transferring data to the bus. Bus clock signals from a master can only be altered when they are stretched by a slow slave device holding down the clock line, or by another master when arbitration occurs.

Two modes:

- Standard mode with bit rate up to 100 Kb/s
- Fast mode with bit rate up to 400 Kb/s

#### 3.10.2.1 I<sup>2</sup>C FIFO management

The transmit and receive paths are buffered with internal FIFO memory enabling up to 16 bytes to be stored independently in both transmit and receive modes. The FIFOs status can be checked using the I<sup>2</sup>C interrupts. There is a programmable threshold value for each FIFO. When the number of entries is greater for the receive FIFO or less for the transmit FIFO, an interrupt is set.

#### 3.10.2.2 I<sup>2</sup>C clock rate calculation

To define the I<sup>2</sup>C clock rate generation there is one register to configure: BRCCR. The clock rate can be calculated using this formula:

$$I2C_{clock} = \begin{cases} \frac{f_{I2C}}{(BRCNT2 * 2) + Foncycle} & \text{in standard mode} \\ \frac{f_{I2C}}{(BRCNT2 * 3) + Foncycle} & \text{in fast mode} \end{cases}$$

Where:

- $f_{I2C}$  is the I<sup>2</sup>C peripheral clock, clocked on the system clock divided by 3.
- BRCNT2 is a field of the BRCCR register.

- Foncycle depends on a programmable field of the CR register:
  - CR: FON = "00" → Filter the clock spike wide = 0 → Foncycle = 1
  - CR: FON = "01" → Filter the clock spike wide = 1 → Foncycle = 3
  - CR: FON = "10" → Filter the clock spike wide = 2 → Foncycle = 4
  - CR: FON = "11" → Filter the clock spike wide = 4 → Foncycle = 6

The minimum input clock frequency for the I<sup>2</sup>C is:

- 1.4 MHz if the I<sup>2</sup>C is in standard mode at 100 kHz.
- 7.2 MHz if the I<sup>2</sup>C is in fast mode at 400 kHz.

### 3.10.2.3 I<sup>2</sup>C configuration

Following a reset, the I<sup>2</sup>C logic is disabled and must be configured when in this state.

The control register (CR) and baud rate register (BRCR) need to be programmed to configure the following parameters of the peripheral:

- Master or slave.
- 7- or 10-bit addressing mode.
- Speed mode.
- Clock rate.

If in slave mode, the SCR register has to be programmed with the selected slave address.

Then, if in master mode, the MCR register is used to define the transaction:

- Read or write.
- Slave addresses (7- or 10-bit) to communicate with.
- Addressing a 7- or 10-bit slave address.
- Stop condition, to generate a stop or restart condition at the end of the transaction (for consecutive transactions).
- Transaction length.

For a master write, the data to transmit have to be written to the transmit FIFO in the I2C\_TFR register. For a master read, when the master transaction is done, data are available in the receive FIFO in I2C\_RFR.

### 3.10.2.4 DMA interface

The I<sup>2</sup>C controller includes a specific DMA interface. The following section describes the signals interface, data flow and programming model for the RX and the TX paths.

The DMA interfaces are separated for each path and two DMA request channels shall be used for a device.

In RX mode, a DMA transfer based on a single descriptor shall be used and the DMA RX channel must be programmed for a peripheral-to-memory transfer where the flow controller is the DMA. Each descriptor is related to a single I<sup>2</sup>C transaction (master read or write-to-slave operation) and no linked list item should be used. The transfer length is programmed on the DMA and the termination of the frame transfer is notified by the assertion of the related interrupt I2C\_RISR:STD or I2C\_RISR:MTD bits. In case of read-from-slave operation, on the DMA (master device) the transfer length shall be programmed according to the I2C\_MCR:LENGTH register field. In case of write-to-slave operation, on the DMA

(slave device) the maximum length (not the real length because it is unknown) shall be programmed.

In TX mode, a DMA transfer based on a single descriptor shall be used and the DMA TX channel must be programmed for a memory-to-peripheral transfer where the flow controller is the DMA. Each descriptor is related to a single I<sup>2</sup>C transaction (master write or read-from-slave operation) and no linked list item should be used. The transfer length is programmed on the DMA and the termination of the frame transfer is notified by the assertion of the related interrupt I<sup>2</sup>C\_RISR:STD or I<sup>2</sup>C\_RISR:MTD bits. In case of write-to-slave operation, on the DMA (master device) the transfer length shall be programmed according to the I<sup>2</sup>C\_MCR:LENGTH register field. In case of read-from-slave operation, on the DMA (slave device) the maximum length (not the real length because it is unknown) shall be programmed.

### 3.10.3 I<sup>2</sup>C registers

I<sup>2</sup>C2 peripheral base address (I<sup>2</sup>C2\_BASE\_ADDR) 0x40A00000

I<sup>2</sup>C1 peripheral base address (I<sup>2</sup>C1\_BASE\_ADDR) 0x40B00000

| 25:15 | LENGTH     | 0x0   | RW | Transaction length. Defines the length, in terms of the number of bytes to be transmitted (MW) or received (MR). In case of write operation, the payload is stored in the Tx FIFO. A transaction can be larger than the Tx FIFO size. In case of read operation the length refers to the number of bytes to be received before generating a not-acknowledge response. A transaction can be larger than the Rx FIFO size. The I <sup>2</sup> C clock line is stretched low until the data in Rx FIFO are consumed. |

| 7:0  | TDATA      | 0x0   | RW | <p>Transmission data. TDATA contains the payload related to a master write or read-from-slave operation to be written in the Tx FIFO. TDATA(0) is the first LSB bit transmitted over the I<sup>2</sup>C line. In case of master write operation, the Tx FIFO shall be preloaded otherwise the I<sup>2</sup>C controller cannot start the operation until data are available.</p> <p>In case of read-from-slave operation, when the slave is addressed, the interrupt RISR:RFSR bit is asserted and the CPU shall download the data in the FIFO. If the FIFO is empty and the I<sup>2</sup>C master is still requiring data, a new request (RISR:RFSE interrupt bit) is asserted to require additional data to the CPU. The slave controller stretches the I<sup>2</sup>C clock line when no data are available for transmission. Since the Tx FIFO could contain some pending data related to the previous transfer (the transfer length may be unknown to the slave controller), the Tx FIFO is self-flushed before asserting the I2C_RISR:RFSR bit. Upon completion of the read-from-slave operation the interrupt bit I2C_RISR:STD is asserted and the related status of the operation is stored in the I2C_SR register. In CPU mode, the FIFO management is based on the assertion of the interrupt bit RISR:TXFNE, related to the nearly-empty threshold.</p> <p>In DMA mode, the single/burst requests are automatically executed based on the number of entries available in the TX FIFO and the related destination burst size programmed in the I2C_DMAR:DBSIZE_TX register field. The DMA requests are terminated at the end of the I<sup>2</sup>C read operation (not acknowledge received by the master) by a dummy last single/burst request.</p> |

| 19:9   | LENGTH     | 0x0   | R  | Transfer length. For an MR, WTS operation the LENGTH field defines the actual size of the subsequent payload, in terms of number of bytes. For an MW, RFS operation the LENGTH field defines the actual number of bytes transferred by the master/slave device. For a WTS operation if the transfer length exceeds 2047 bytes, the operation is stopped by the slave returning a NACK handshake and the flag OVFL is set. For an RFS operation if the transfer length exceeds 2047 bytes, the operation continues normally but the LENGTH field is reset to 0. |

| 7:0  | RDATA      | 0x0   | R  | Receive data. RDATA contains the received payload, related to a master read or write-to-slave operation, to be read from the Rx FIFO. The RDATA(0) is the first LSB bit received over the I2C line. In case the FIFO is full, the I2C controller stretches automatically the I2C clock line until a new entry is available.<br>For a write-to-slave operation, when the slave is addressed, the interrupt I2C_RISR:WTSR bit is asserted for notification to the CPU. In CPU mode the FIFO management shall be based on the assertion of the interrupt bit I2C_RISR:RXFNF, related to the nearly-full threshold.<br>In DMA mode, the single requests are automatically executed based on the number of entries contained in the Rx FIFO. |

|-----|------------|-------|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | TXFE       | 0x1   | R  | TX FIFO empty. TXFE is set when TX FIFO is empty. This bit is self-cleared by writing in TX FIFO.<br>0: TX FIFO is not empty.<br>1: TX FIFO is empty.                                                                                                                                                                                                                                                                                                                                                                                    |
| 1   | TXFNE      | 0x1   | R  | TX FIFO nearly empty. TXFNE is set when the number of entries in TX FIFO is less than or equal to the threshold value programmed in the I2C_TFTR:THRESHOLD_TX register. It is self-cleared when the threshold level is over the programmed threshold.<br>0: Number of entries in TX FIFO greater than the TFTR:THRESHOLD_TX register.<br>1: Number of entries in TX FIFO less than or equal to the TFTR:THRESHOLD_TX register.                                                                                                           |
| 2   | TXFF       | 0x0   | R  | TX FIFO full. TXFF is set when a full condition occurs in TX FIFO. This bit is self-cleared when the TX FIFO is not full:<br>0: TX FIFO is not full.<br>1: TX FIFO is full.                                                                                                                                                                                                                                                                                                                                                              |
| 3   | TXFOVR     | 0x0   | R  | TX FIFO overrun. TXFOVR is set when a write operation in TX FIFO is performed and TX FIFO is full. The application must avoid an overflow condition by a proper data flow control. Anyway in case of overrun, the application shall flush the transmitter (CR:FTX bit to set) because the TX FIFO content is corrupted (at least one word has been lost in FIFO). This interrupt is cleared by setting the related bit of the ICR register:<br>0: No overrun condition occurred in TX FIFO.<br>1: Overrun condition occurred in TX FIFO. |
| 4   | RXFE       | 0x1   | R  | RX FIFO empty. RXFE is set when the RX FIFO is empty. This bit is self-cleared when the slave RX FIFO is not empty:<br>0: RX FIFO is not empty.<br>1: RX FIFO is empty.                                                                                                                                                                                                                                                                                                                                                                  |
| 5   | RXFNF      | 0x0   | R  | RX FIFO nearly full. RXFNF is set when the number of entries in RX FIFO is greater than or equal to the threshold value programmed in the RFTR:THRESHOLD_RX register. Its self-cleared when the threshold level is under the programmed threshold:<br>0: Number of entries in the RX FIFO less than the RFTR:THRESHOLD_RX register.<br>1: Number of entries in the RX FIFO greater than or equal to the RFTR:THRESHOLD_RX register.                                                                                                      |

| Bit  | Field name | Reset | RW | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 6    | RXFF       | 0x0   | R  | RX FIFO full. RXFF is set when a full condition occurs in RX FIFO. This bit is self-cleared when the data are read from the RX FIFO.<br>0: RX FIFO is not full.<br>1: RX FIFO is full.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15:7 | RESERVED   | 0x0   | R  | RESERVED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 16   | RFSR       | 0x0   | R  | Read-from-slave request. RFSR is set when a read-from-slave "Slavetransmitter" request is received (I <sup>2</sup> C slave is addressed) from the I <sup>2</sup> C line. On the assertion of this interrupt the TX FIFO is flushed (pending data are cleared) and the CPU shall put the data in TX FIFO. This bit is self-cleared by writing data in FIFO. In case the FIFO is empty before the completion of the read operation, the RISR:RFSE interrupt bit is set. This interrupt is cleared by setting the related bit of the ICR register.<br>0: Read-from-slave request has been served.<br>1: Read-from-slave request is pending.                                                                                                                                                                                   |
| 17   | RFSE       | 0x0   | R  | Read-from-slave empty. RFSE is set when a read-from-slave operation is in progress and TX FIFO is empty. On the assertion of this interrupt, the CPU shall download in TX FIFO the data required for the slave operation. This bit is self-cleared by writing in TX FIFO. At the end of the read-from-slave operation this bit is cleared although the TX FIFO is empty.<br>0: TX FIFO is not empty.<br>1: TX FIFO is empty with the read-from-slave operation in progress.                                                                                                                                                                                                                                                                                                                                                |
| 18   | WTSR       | 0x0   | R  | Write-to-slave request. WTSR is set when a write-to-slave operation is received (I <sup>2</sup> C slave is addressed) from the I <sup>2</sup> C line. This notification can be used by the application to program the DMA descriptor when required. This interrupt is cleared by setting the related bit of the ICR register:<br>0: No write-to-slave request pending.<br>1: Write-to-slave request is pending.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 19   | MTD        | 0x0   | R  | Master transaction done. MTD is set when a master operation (master write or master read) has been executed after a stop condition. The application shall read the related transaction status (SR register), the pending data in the RX FIFO (only for a master read operation) and clear this interrupt (transaction acknowledgment). A subsequent master operation can be issued (writing the MCR register) after the clearing of this interrupt. A subsequent slave operation will be notified (RISR:WTSR and RISR:RFSR interrupt bits assertion) after clearing this interrupt, meanwhile the I <sup>2</sup> C clock line is stretched low. This interrupt is cleared by setting the related bit of the ICR register.<br>0: Master transaction acknowledged.<br>1: Master transaction done (ready for acknowledgment). |

| Bit   | Field name | Reset | RW | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 24    | MAL        | 0x0   | R  | <p>Master arbitration lost. MAL is set when the master loses the arbitration. The status code word in the SR contains a specific error tag (CAUSE field) for this error condition. A collision occurs when 2 stations transmit simultaneously 2 opposite values on the serial line. The station that is pulling up the line, identifies the collision reading a 0 value on the sda_in signal, stops the transmission, leaves the bus and waits for the idle state (STOP condition received) on the bus line before retrying the same transaction. The station which transmits the first unique zero wins the bus arbitration. This interrupt is cleared by setting the related bit of the ICR register.</p> <p>0: No master arbitration lost.<br/>1: Master arbitration lost.</p>                                                                                                        |
| 25    | BERR       | 0x0   | R  | <p>Bus Error. BERR is set when an unexpected Start/Stop condition occurs during a transaction. The related actions are different, depending on the type of operation in progress. The status code word in the SR contains a specific error tag (CAUSE field) for this error condition. This interrupt is cleared by setting the related bit of the ICR register.</p> <p>0: No bus error detection.<br/>1: Bus error detection.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

All RESERVED fields inside registers must always be written with their default value.

## 3.11 Flash controller

### 3.11.1 Flash controller introduction

The BlueNRG-1 integrates a Flash controller to interface the embedded Flash memory.

Main features are:

- Sector erase and mass erase
- 256 Kbyte Flash memory: 128 pages of 8 rows with 64 words each
- Flash programming
- Mass read
- Enable readout protection
- 32-bit read access
- 32-bit write access in single write and 4x32-bit in burst write (reduce programming time by 2)

### 3.11.2 Flash controller functional description

The BlueNRG-1 embeds up to 160 KB (40960 x 32-bit) of internal Flash memory. A Flash interface implements instruction access and data access based on the AHB protocol. It implements the logic necessary to carry out the Flash memory operations (Program/Erase) controlled through the Flash registers.

Writing to Flash only allows clearing bits from '1' to '0'. This means any write from '0' to '1' implies erasing before performing a write.

Flash memory is composed of 80 pages containing 8 rows of 64 words (80 x 8 x 64 = 40960 words). Each word is 32-bit = 4 bytes long which means 160 kB of Flash.

The address inside the ADDRESS register is built as follows:

ADDRESS[13:0] = XADR[9:0] & YADR[5:0] with:

- XADR[9:3] = page address
- XADR[2:0] = row address
- YADR[5:0] = word address (one word = four bytes)

One specific address can be written only twice between two erase actions even if each writing only clears bits.

The Flash data retention is greater than 10 years at 85 °C. The Flash is rated to have a Flash cycling of 10.000 write/erase cycles.

#### 3.11.2.1 Reading Flash memory

To read one single word of the flash, just read it as if RAM memory: read the desired flash address and get read data on the bus.

### 3.11.2.2 Erasing Flash

The Flash controller allows erasing one page or the full main Flash.

ERASE sequence (erase one page):

1. Write the page address to be erased by writing in the ADDRESS register the following value:
  - a. ADDRESS[15:9] = XADR[9:3] = page address to erase
  - b. ADDRESS[8:0] = 9'b0 (row and word addresses at zero).
2. Write the ERASE command (0x11) in the COMMAND register.
3. Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating command is taken into account and under execution.
4. Clear the CMDSTART flag by writing CMDSTART to '1' in the IRQSTAT register.
5. Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed.
6. Clear the CMDDONE flag by writing CMDDONE to '1' in the IRQSTAT register.

After this command, the erased page contains only bits set to '1'.

MASSERASE sequence (erase completely main flash):

1. Write the MASSERASE command (0x22) in the COMMAND register.
2. Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution.
3. Clear the CMDSTART flag by writing CMDSTART to '1' in the IRQSTAT register.
4. Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed.
5. Clear the CMDDONE flag by writing CMDDONE to '1' in the IRQSTAT register.

After this command, the full main Flash contains only bits set to '1'.

### 3.11.2.3 Write function examples

The Flash Controller allows writing one word (WRITE), up to 4 words (BURSTWRITE) or the full main Flash memory (with a single fixed word).

Note: As a write can only program to '0' on bits already set to '1', it is necessary to erase the page and request that the bits be set to '1' (instead of '0') in order to re-write to '0'.

#### WRITE sequence:

1. Indicate the location to write by filling the ADDRESS register with the targeted address (page, row and word number)
2. Write the value to program in the DATA register.
3. Write the WRITE command (0x33) in the COMMAND register.
4. Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution.
5. Clear the CMDSTART flag by writing CMDSTART to '1' in the IRQSTAT register.
6. Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed.
7. Clear the CMDDONE flag by writing CMDDONE to '1' in the IRQSTAT register.

#### BURSTWRITE sequence:

1. Indicate the location to write by filling the ADDRESS register with the targeted address of the first data to write (page, row and word number). DATA0 will be written and ADDRESS, DATA1 at ADDRESS+1 and so on. (Write the values to program in the DATA0-3 registers. To write less than four words, write 0xFFFFFFFF in the unused DATA1-3 registers.)

2. Write the BURSTWRITE command (0xCC) in the COMMAND register.
3. Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution.
4. Clear the CMDSTART flag by writing CMDSTART to '1' in the IRQSTAT register.
5. Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed.
6. Clear the CMDDONE flag by writing CMDDONE to '1' in the IRQSTAT register.

### 3.11.2.4 Flash readout protection

It is possible to protect flash memory from unwanted access while in debug mode, this is normally used to avoid copy or reverse engineering of a deployed application in the market.

If the readout protection mechanism is activated, as soon as Cortex-M0 is halted, any access to Flash memory will return a fixed 0x0 value and generate an AHB error if a debugger tries to read it.

Note that RAM memory debug accesses are also disabled by this lock protection.

Enabling readout protection:

1. Program a secret 64 bit sequence in the last two word address of the user flash. The secret 64 bit sequence can be anything different from 0xFFFFFFFF, 0xFFFFFFFF.

Disable readout protection:

1. Perform a mass erase of the user flash

### 3.11.2.5 Flash command list

The valid command values list for the COMMAND register is reported in the table below.

**Table 110: Flash commands**

| Command name | Description                                                  | Value |
|--------------|--------------------------------------------------------------|-------|
| ERASE        | Erase page defined by register ADDRESS                       | 0x11  |
| MASSERASE    | Mass erase (Flash is completely erased)                      | 0x22  |
| WRITE        | Program one location (defined by registers DATA and ADDRESS) | 0x33  |
| BURSTWRITE   | Burst write operation                                        | 0xCC  |

### 3.11.2.6 Flash interface timing characteristics

**Table 111: Flash interface timing**

| Description                                    | Min. | Unit |
|------------------------------------------------|------|------|
| Page erase time                                | 21.5 | ms   |
| Mass erase time                                | 21.5 | ms   |
| Program time WRITE                             | 44   | µs   |
| Program time BURSTWRITE <sup>(1)</sup> 1 word  | 44   | µs   |
| Program time BURSTWRITE <sup>(1)</sup> 2 words | 65   | µs   |
| Program time BURSTWRITE <sup>(1)</sup> 3 words | 86   | µs   |
| Program time BURSTWRITE <sup>(1)</sup> 4 words | 107  | µs   |

**Notes:**

<sup>(1)</sup>Burst write procedure skips the 0xFFFF\_FFFF word

### 3.11.3 Flash controller registers

Flash controller peripheral base address (FLASH\_BASE\_ADDR) 0x40100000.

**Table 112: FLASH controller registers**

| Address offset | Name     | RW | Reset      | Description                                                               |

## 3.12 GPIO

### 3.12.1 Introduction

The BlueNRG-1 offers 14 GPIOs (WCSP34 package) or 15 GPIOs (QFN32 package).

The programmable I/O pin can be configured for operating as:

- Programmable GPIOs
- Peripheral input or output line of standard communication interfaces
- PDM processor data/clock
- 2 PWM sources (PWM0 and PWM1 independently configurable) and 4 PWM output pins (IO2, IO3, IO4 and IO5).
- 5 wake-up sources from standby and sleep mode
- Each I/O can generate an interrupt independently to the selected mode. Interrupts are generated depending on a level or edge

### 3.12.2 Functional description

In the table below is reported the GPIO configuration table where at each IO pin is associated the related functions.

Table 124: IO functional map

| Pin name <sup>(1)</sup> | GPIO mode "000" |                       | Mode serial1 '001' |          | Mode serial0 '100' |          | Mode serial2 '101' |          |
|-------------------------|-----------------|-----------------------|--------------------|----------|--------------------|----------|--------------------|----------|
|                         | Type            | Signal                | Type               | Signal   | Type               | Signal   | Type               | Signal   |
| IO0                     | I/O             | GPIO 0                | I                  | UART_CTS | I/O                | SPI_CLK  | -                  | -        |

| IO9                     | I/O             | GPIO 9                | I                  | SWCLK    | I                  | SPI_IN   | -                  | -        |
| IO10                    | I/O             | GPIO 10               | I                  | SWDIO    | O                  | SPI_OUT  | -                  | -        |
| IO11                    | I/O             | GPIO 11               | I                  | UART_RXD | I/O                | SPI_CS1  | -                  | -        |
| IO12                    | OD              | GPI 12 <sup>(2)</sup> |                    | -        | I/O                | I2C1_CLK | -                  | -        |
| IO13                    | OD              | GPI 13 <sup>(2)</sup> | I                  | UART_CTS | I/O                | I2C1_DAT | -                  | -        |
| IO14                    | I/O             | GPIO 14               | I/O                | I2C1_CLK | I/O                | SPI_CLK  | -                  | -        |

**Notes:**

<sup>(1)</sup>All the I2C pins require external pull-up

<sup>(2)</sup>IO12 and IO13 can only be General Purpose Input pins (not output).

### 3.12.2.1 GPIO interrupts

Each IO in GPIO mode can be used as interrupt source from external signal. The trigger event is both edge and level sensitive according to configuration. All the configuration are reported in table below.

Table 125: GPIO interrupt modes

| Configuration | Interrupt mode |             |            |           |            |
|---------------|----------------|-------------|------------|-----------|------------|
|               | Falling edge   | Rising edge | Both edges | Low level | High level |
| IOIS          | 0              | 0           | 0          | 1         | 1          |
| IOIBE         | 0              | 0           | 1          | NA        | NA         |
| IOIEV         | 0              | 1           | NA         | 0         | 1          |

The interrupt is enabled by writing 1 in the IO\_MIS register, in the position with same number of the IO desired. Once the interrupt occurs, it can be cleared by writing 1 in the IO\_IC register. All the interrupts drive a single interrupt signal of the NVIC.

### 3.12.2.2 GPIO characteristics

By default all the GPIO pins are configured as input with related pull-up or pull-down resistor enabled according to table below.

Table 126: Pin characteristics

| Name | Type | Buffer strength <sup>(1)</sup> | Pull-up / pull-down availability | Reset state     | Default state        |
|------|------|--------------------------------|----------------------------------|-----------------|----------------------|
| IO0  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO1  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO2  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO3  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO4  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO5  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO6  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO7  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO8  | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |
| IO9  | I/O  | Low / high drive               | Pull- up                         | Input pull-up   | Mode serial1 (SWCLK) |
| IO10 | I/O  | Low / high drive               | Pull- up                         | Input pull-up   | Mode serial1 (SWDIO) |
| IO11 | I/O  | Low / high drive               | Pull-up                          | Input pull-up   | GPIO mode            |
| IO12 | I    | 10 mA                          | No pull                          | Input           | GPIO mode            |
| IO13 | I    | 10 mA                          | No pull                          | Input           | GPIO mode            |
| IO14 | I/O  | Low / high drive               | Pull-down                        | Input pull-down | GPIO mode            |

**Notes:**

<sup>(1)</sup>See [Table 205: "Digital I/O specifications"](#)

All the IOs are in high impedance under reset. In low power modes (sleep and standby) the IOs are configured as follows:

- IO0 to IO8 and IO14 are in high impedance state
- IO9, IO10, IO11 are in input state w/o internal pull according to IO configuration
- IO12 , IO13 are in input state no pull

If IO12 or IO13 is not used, it must be put at GND through pull-down resistor.

As DIO14 is internally bound with the ANATEST0 signal, a short positive pulse of about 75  $\mu$ s is generated at the device reset.

Table 127: IO pull values

| Name                                       | Description name | Min. | Typ. | Max. | Unit |
|--------------------------------------------|------------------|------|------|------|------|
| Digital input and output when 1.8 V supply |                  |      |      |      |      |
| RPD                                        | Pull-down value  | 117  | 202  | 363  | kΩ   |
| RPU                                        | Pull-up value    | 135  | 211  | 334  |      |
| Digital input and output when 3.3V supply  |                  |      |      |      |      |
| RPD                                        | Pull-down value  | 53   | 84   | 144  | kΩ   |
| RPU                                        | Pull-up value    | 57   | 81   | 122  |      |

### 3.12.3 GPIO registers

GPIO peripheral base address (GPIO\_BASE\_ADDR) 0x40000000.

**Table 128: GPIO registers**

| Address offset | Name  | RW | Reset      | Description                                                                                                                                                                                     |
|----------------|-------|----|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

All RESERVED fields inside registers must always be written with their default value.

## 3.13 MFT

### 3.13.1 MFT introduction

The BlueNRG-1 integrates two multi functions timers (MFT).

Main features are:

- Two 16-bit programmable timer/counters.
- Two 16-bit reload/capture registers that function either as reload registers or as capture registers, depending on the mode of operation.
- An 8-bit fully programmable clock prescaler.
- Clock source selectors that allow each counter to operate in:
  - Pulse-accumulate mode
  - External-event mode
  - Prescaled system clock mode
  - Slow clock input mode (available only if 32 MHz system clock is used, allows to divide by 2 and obtains a 16 MHz system clock as clock source).
- Two I/O pins (TnA and TnB) with programmable edge detection that operate as:
  - Capture and preset inputs
  - External event (clock) inputs
  - PWM outputs.
- Two interrupts, one for each counter, that can be triggered by a:
  - Timer underflow
  - Timer reload
  - Input capture
  - Pulse train for generation of single or multiple PWM pulses.

### 3.13.2 MFT functional description

The MFT can be configured in five different modes. At each mode is associated a particular function for the two timers both for counter and reload registers as reported in [Table 144: "MFT modes"](#).

**Table 144: MFT modes**

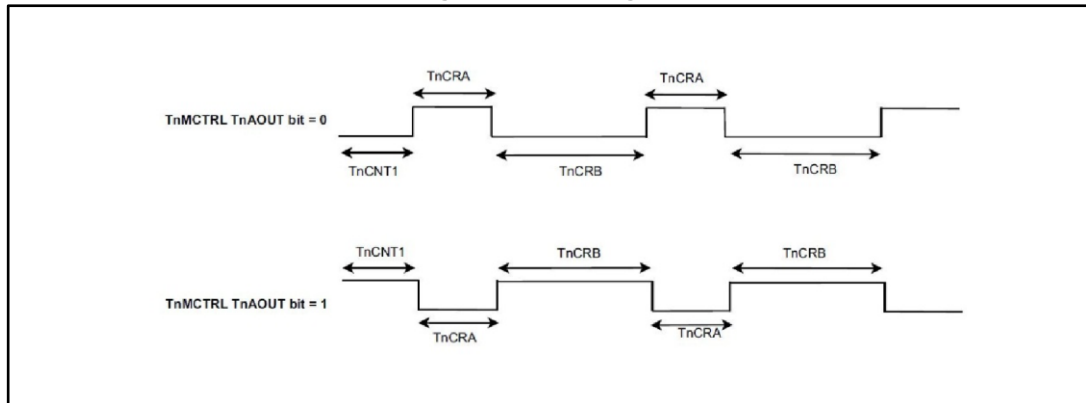

| Mode | Description                                    | Timer Counter 1 (TnCNT1)  | Reload / capture A (TnCRB)                   | Reload / Capture B (TnCRB)                   | Timer Counter 2 (TnCNT2)      |
|------|------------------------------------------------|---------------------------|----------------------------------------------|----------------------------------------------|-------------------------------|
| 1    | PWM and system timer or external event counter | Counter for PWM           | Auto reload A = PWM time 1                   | Auto reload B = PWM time 2                   | System time or external event |
| 1a   | PWM pulse train                                | Counter for PWM           | Auto reload A = PWM time 1                   | Auto reload B = PWM time 2                   | Pulse counter                 |

#### 3.13.2.1 MFT mode 1: processor-independent PWM

In Mode1, the timer counter 1 (TnCNT1) can be used to generate a PWM signal on an output pin of the device. In this mode, the PWM output can emulate a clock signal with customized duty-cycle. Indeed, the TnCNT1 is alternatively reloaded by TnCRB and TnCRB registers. The initial value of the PWM output signal can be selected by software to

be either high or low thanks to the TnAOUT bit in TnMCTRL register. This bit impacts which reload value, is used for high level and low level of the PWM signal as shown in [Figure 15: "PWM signal"](#) below.

**Figure 15: PWM signal**

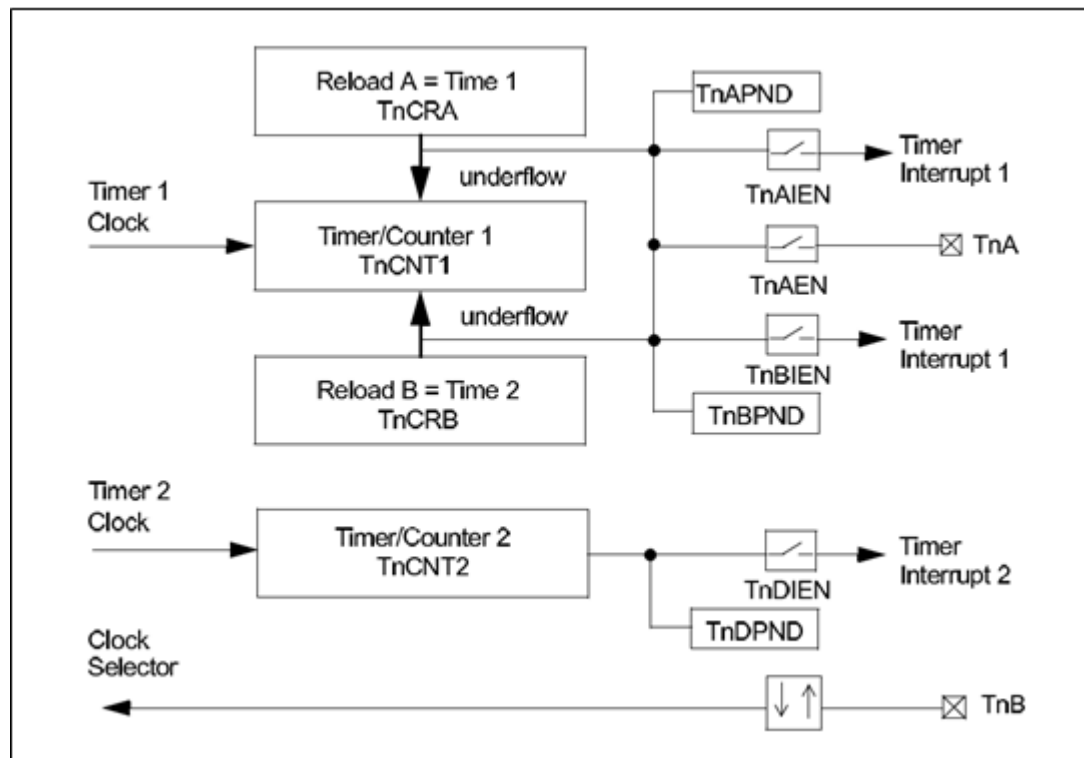

When started the first time, the TnCNT1 starts with value preprogrammed in the register and count down at the clock rate selected by the Timer/counter 1 clock selector (TnCKC register). When an underflow occurs, the TnCNT1 is reloaded alternatively with TnCRB and TnCRB registers (in this order) and counting proceeds downward from the loaded value.

Any time the counter is stopped by choosing "no-clock" by the timer/counter 1 clock selector, it obtains its first reload value after it has been started again from the TnCRB register. Each time the counter is stopped and then restarted, it obtains its first reload value from the TnCRB register. This is true whether the timer is restarted upon reset, after entering mode 1 from another mode, or after stopping and restarting the clock with the Timer/counter1 clock selector.

In figure below the block diagram related to the MFT mode 1.

Figure 16: MFT mode 1 block diagram

In this mode, the timer toggles the TnA output upon underflow which is connected to PWMx pin of the BlueNRG1. This generates a clock signal on TnA with the width and duty cycle controlled by the values stored in the TnCRA and TnCRB registers.

This is a "processor-independent" PWM clock because once the timer is set up, no more interaction is required from the software and the CPU in order to generate the PWM signal.

The timer can generate separate interrupts upon reload from TnCRB and TnCRA. The TnAPND or TnBPND flags, which are set by the hardware upon occurrence of a timer reload, indicate which interrupt has occurred.

In this mode of operation, Timer/counter 2 can be used as a simple system timer or an external-event counter. Counter TnCNT2 counts down with the clock selected by the Timer/counter 2 clock selector, and can be configured to generate an interrupt upon underflow if enabled by the TnDIEN bit.

The interrupts can be enabled or disabled by software.

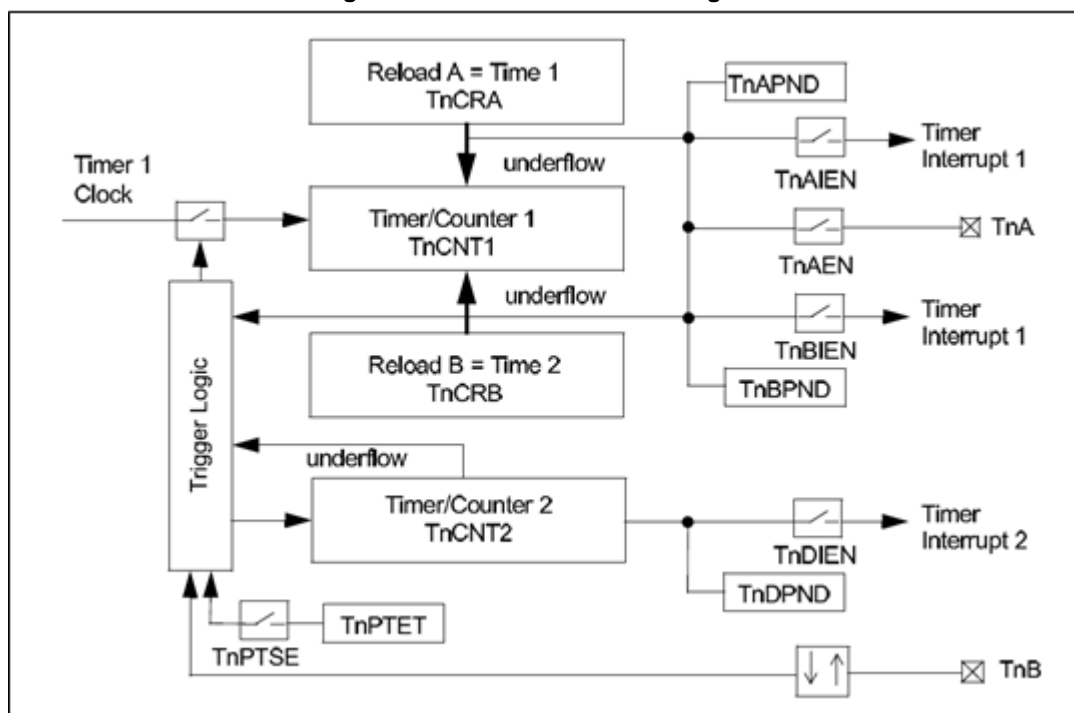

### 3.13.2.2 MFT mode 1a: PWM pulse-train mode

Mode1a is used to output a PWM signal thanks to timer/counter 1 as for Mode1 but only in a time window defined by the Timer/counter2. Indeed, the Timer/counter2 is used to specify the number of pulses to output on the IO. The Mode1a corresponds to the Mode1 selected in the TnMDSEL field of TnMCTRL register with in addition the TnPEN bit set in the TnMCTRL register. In Mode1a, the timer/counter 1 (TnCNT1) alternatively is reloaded by TnCRA and TnCRB registers after starting from TnCNT1 as for Mode1 and toggle the TnA output of the MFT connected to PWMx IO each time an underflow occurs. In parallel, a trigger pulse is sent to Timer/Counter 2 (TnCNT2), decrementing it by one. If timer/counter 2 (TnCNT2) has reached the underflow condition and the end-of-pulse condition is

detected by the trigger logic as well, the clock of timer/counter 1 (TnCNT1) is disabled immediately.

The figure below shows the block diagram related to the MFT mode 1a.

**Figure 17: MFT mode 1a block diagram**

In Mode 1a, timer/counter 2 (TnCNT2) behaves differently from the way it behaves in modes 1 to 4. If an underflow condition occurs, the counter is preset to 0x0000 and not 0xFFFF.

The timer/counter 1 starts to count:

- either on an external event on TnB input,
- or by software if TnPTSE bit has been set by setting the TnPTET bit.

The start of count request through TnPTET bit setting when software trigger option is chosen must be done after the MFT is enabled (TnEN bit in TnMCTRL register).

Any time the counter is stopped by choosing "no-clock" by the timer/counter 1 clock selector (TnCKC register), it obtains its first reload value after it has been started again from the TnCRB register. Upon reset, the MFT is disabled. Every time this mode is entered, the first reload in this mode will be from register TnCRB. Once the underflow condition for TnCNT2 has been reached, TnCNT2 must be initialized again by the application. It is not reloaded by any reload register.

Timer/counter 2 can be configured to generate an interrupt upon underflow if enabled by the TnDIEN bit.

In pulse-train mode, the value of TnCNT2 specifies the number of pulses to be generated, plus one additional pulse (TnCNT2+1 number of pulses).

In pulse-train mode, the trigger logic uses events on TnB to enable the timer/counter 1 clock. This function has to be enabled by setting the TnPTSE bit to 0.

TnB can be configured to sense either positive-going or negative-going transitions.

Timer/Counter 1 can be configured to toggle the TnA output bit upon underflow. This results in the generation of a pulse signal on TnA, with the width and duty cycle controlled by the values stored in the TnCRB and TnCRB registers. This is a processor-independent PWM signal because once the timer is set up, no more interaction is required from the software or the CPU in order to generate one or more PWM signal pulses. The initial value of the PWM output signal can be selected by software to be either high or low.

The timer can be configured to generate separate interrupts upon reload from TnCRB and TnCRB. The TnAPND or TnBPND flags, which are set by the hardware upon occurrence of a timer reload, indicate which interrupt has occurred. The interrupts can be enabled or disabled under software control.

### 3.13.2.3 MFT mode 2: dual-input capture mode

The Mode2 is used to capture transitions on two selected input pads of the device. The Timer/Counter1 can be used to manage the dual-capture feature as follows:

- A transition on input pad connected to TnA pin of the MFT generates a transfer of TnCNT1 register value in TnCRB register.
- A transition on input pad connected to TnB pin of the MFT generates a transfer of TnCNT1 register value in TnCRB register.

The Timer/counter2 can be used:

- As a system counter: to count down at the rate of the selected clock.

Note: the device input pad selection is done using MFTX\_IOSEL register.

The transition edge to capture has to be defined in TnAEDG and TnBEDG bits of the TnMCTRL register.

The TnA and TnB inputs can be configured to perform a counter pReset to 0xFFFF upon reception of a valid capture event using TnAEN and TnBEN bits in TnMCTRL register. In this case, the current value of the counter is transferred to the corresponding capture register and then the counter is pReset to 0xFFFF. Using this approach directly allows the software to determine the on-time, off-time, or period of an external signal, while reducing CPU overhead.

In [Figure 18: "MFT mode 2 block diagram"](#) below the block diagram related to the MFT mode 2.

Figure 18: MFT mode 2 block diagram

The input signal on TnA and TnB must have a pulse width equal to or greater than one system clock cycle. The values captured in the TnCRB register at different times reflect the elapsed time between transitions on the TnA pin. The same is true for the TnCRB register and TnB pin. Each input pin can be configured to sense either positive-going or negative-going transitions.

The timer can be configured to generate interrupts on reception of a transition on either TnA or TnB, which can be enabled or disabled separately by the TnAIEN and TnBIEN bits. An underflow of TnCNT1 can generate an interrupt if enabled by the TnCIEN bit.

Timer/counter 2 can be used as a simple system timer in this mode of operation. TnCNT2 counts down with the clock selected by the Timer/counter 2 clock selector, and can be configured to generate an interrupt upon underflow if enabled by the TnDIEN bit.

TnCNT1 cannot operate in the pulse-accumulate or external-event counter modes, since the TnB input is used as a capture input. Selecting either of these modes for TnCNT1 causes TnCNT1 to be stopped. However, all available clock source modes may be selected for TnCNT2. Thus, it is possible to determine the number of capture events on TnB or the elapsed time between capture events on TnB by using TnCNT2.

#### 3.13.2.4 MFT mode 3: dual independent timer/counter mode

This Mode3 allows using the two timer/counter 1 and 2 separately.

The timer/counter1 can be used:

- As a system counter: to count down at the rate of the selected clock.

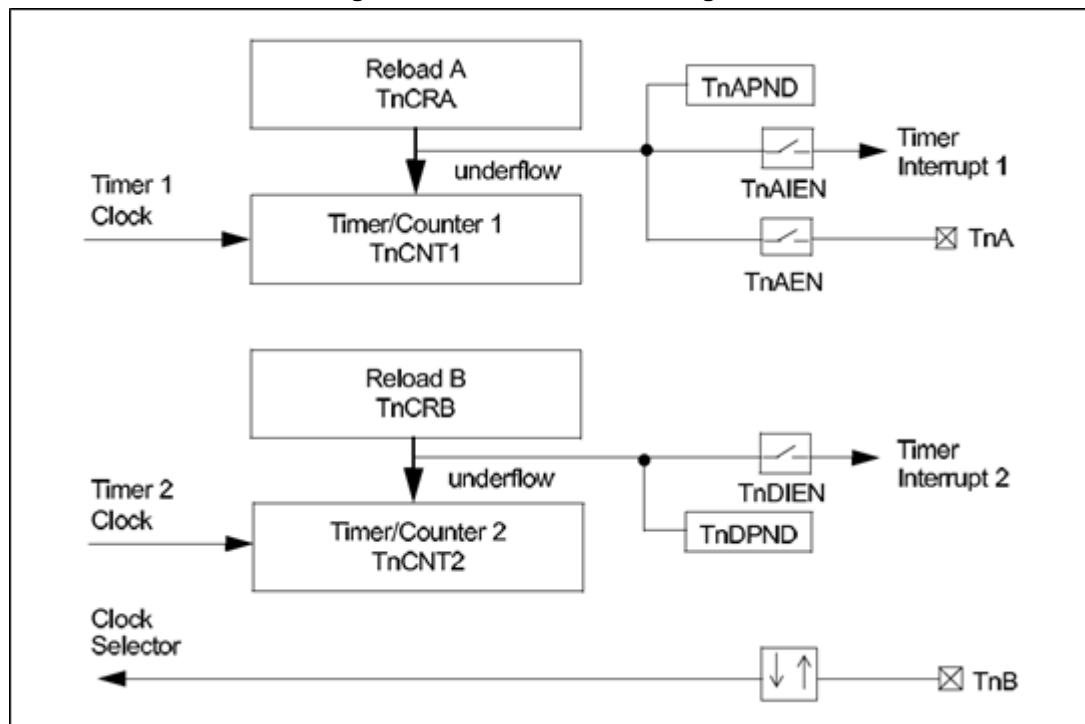

- To generate a 50% duty-cycle clock signal on TnA pin connected to the PWMx pin of the device (TnCNT1 reloaded by TnCRB on underflow).
- To be an event counter using TnB pin as an external event or pulse-accumulate input.

The timer/counter2 can be used:

- As a system counter: to count down at the rate of the selected clock.
- To be an event counter using TnB pin as an external event or pulse-accumulate input.

In figure below the block diagram related to the MFT mode 3.

**Figure 19: MFT mode 3 block diagram**

In Mode 3, the timer/counter is configured to operate as a dual independent system timer or dual external-event counter. In addition, timer/counter 1 can generate a 50% duty cycle PWM signal on the TnA pin. The TnB pin can be used as an external-event input or pulse-accumulate input, and serve as the clock source to either Timer/Counter 1 or Timer/Counter 2. Both counters can also be operated from the prescaled system clock.

Timer/Counter 1 (TnCNT1) counts down at the rate of the selected clock. Upon underflow, TnCNT1 is reloaded from the TnCRB register and counting proceeds. If enabled, the TnA pin toggles upon underflow of TnCNT1. The initial value of the TnA output can be selected by software to be either high or low. In addition, the TnAPND interrupt-pending flag is set, and a timer interrupt 1 is generated if the TnAIEN bit is set. Since TnA toggles upon every underflow, a 50% duty-cycle PWM signal can be generated on TnA without requiring any interaction of the software or the CPU.

Timer/Counter 2 (TnCNT2) counts down at the rate of the selected clock. Upon every underflow of TnCNT2, the value contained in the TnCRB register is loaded into TnCNT2 and counting proceeds downward from that value. In addition, the TnDPND interrupt-pending flag is set and a timer interrupt 2 is generated if the TnDIEN bit is set.

### 3.13.2.5 MFT mode 4: input-capture plus timer mode

This Mode4 is combination of Mode3 and Mode2.

The timer/counter1 can be used:

- As a system counter: to count down at the rate of the selected clock.
- To generate a 50% duty-cycle clock signal on TnA pin connected to the PWMx pin of the device (TnCNT1 reloaded by TnCRB on underflow).

The Timer/Counter2 can be used:

- As a system counter: to count down at the rate of the selected clock.
- A transition on input pad connected to TnB pin of the MFT generates a transfer of TnCNT2 register value in TnCRB register.

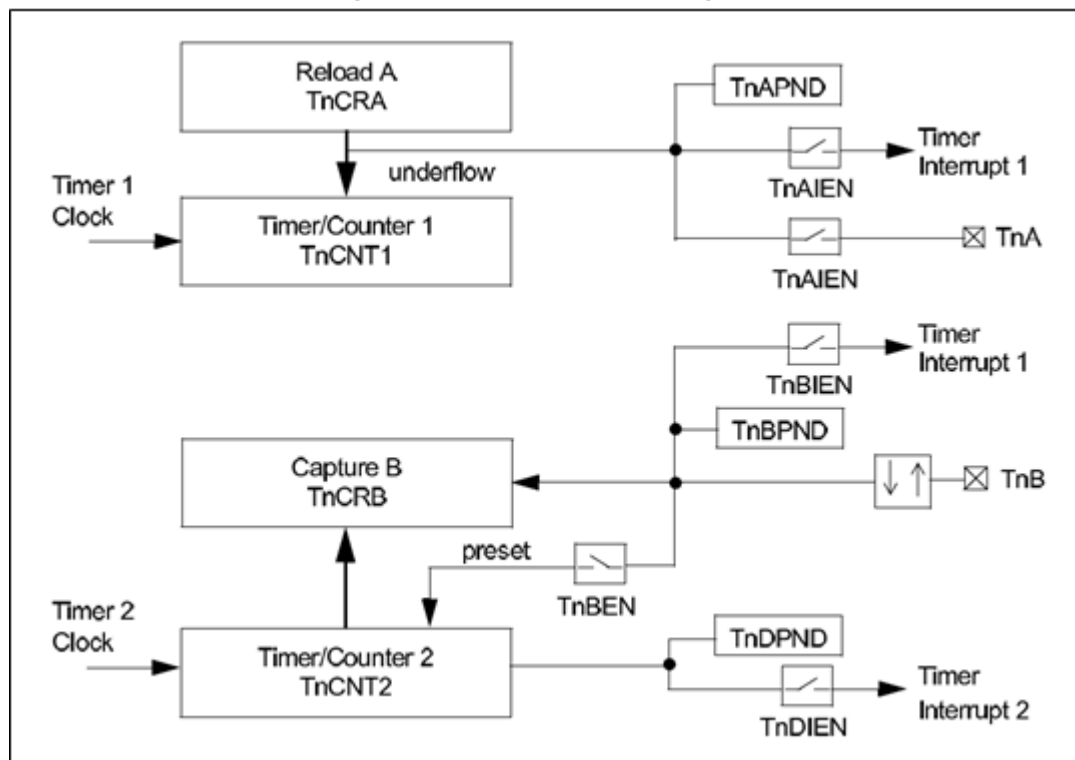

The device input pad selection is done using MFTX\_IOSEL register

The transition edge to capture has to be defined in TnBEDG bit of the TnMCTRL register. The TnB input can be configured to perform a counter pReset to 0xFFFF upon reception of a valid capture event using TnBEN bit in TnMCTRL register.

In figure below the block diagram related to the MFT mode 4.

**Figure 20: MFT mode 4 block diagram**

This mode is a combination of mode 3 and mode 2, and makes it possible to operate timer/counter 2 as a single input-capture timer while Timer/Counter 1 can be used as a system timer as described above.

TnCNT1 starts counting down once a clock has been enabled. Upon underflow, TnCNT1 is reloaded from the TnCRB register, and counting proceeds downward from that value. If enabled, the TnA pin toggles upon every underflow of TnCNT1. The initial value of the TnA output signal can be selected by software to be either high or low. In addition, the TnAPND interrupt-pending flag is set and a timer interrupt 1 is generated if the TnAIEN bit is set.

Since TnA toggles upon every underflow, a 50% duty-cycle PWM signal can be generated on TnA without requiring any interaction with the software or the CPU.

TnCNT2 starts counting down once a clock has been enabled. When a transition is received on TnB, the value contained in TnCNT2 is transferred to TnCRB, and the interrupt-pending flag TnBPND is set. A timer interrupt 1 is generated if enabled. The software can enable a pReset of the counter to 0xFFFF upon detection of a transition on TnB. In this case, the current value of TnCNT2 is transferred to TnCRB, followed by a pReset of the counter to 0xFFFF. TnCNT2 starts counting downwards from 0xFFFF until the next transition is received on TnB, which causes the procedure of capture and pReset to be repeated. The underflow of TnCNT2 causes the TnDPND interrupt-pending flag to be set, and can also generate a timer interrupt 2 if enabled. The input signal on TnB must have a pulse width equal to or greater than one system clock cycle. TnB can be configured to sense either rising or falling edges. TnCNT2 cannot operate in the pulse-accumulate or external-event counter modes since the TnB input is used as a capture input. Selecting either of these modes for TnCNT2 causes TnCNT2 to be stopped. However, all available clock source modes may be selected for TnCNT1. Thus by using TnCNT1, it is possible to determine the number of capture events on TnB, or the elapsed time between capture events on TnB.

### 3.13.2.6 Timer IO functions

There are two pins associated with each instance of the MFTX. The pins are called TnA and TnB. The functionality of TnA and TnB depends on the mode of operation and the value of the TnAEN and TnBEN bits. [Table 145: "MFT IO functions"](#) shows the function of TnA and TnB for various modes of operation. Note that if TnA functions as a PWM output, TnAOUT defines the initial and present value of TnA. For example, if the user wishes to start with TnA high, TnAOUT needs to be set before enabling the timer clock.

**Table 145: MFT IO functions**

| Pin | TnAEN<br>TnBEN         | Mode 1                                   | Mode 1a                              | Mode 2                                      | Mode 3                                   | Mode 4                                      |
|-----|------------------------|------------------------------------------|--------------------------------------|---------------------------------------------|------------------------------------------|---------------------------------------------|

| TnB | TnAEN = X<br>TnBEN = 0 | External event or pulse accumulate input | External event if TnPTSE = 0         | Capture TnCNT1 into TnCRB                   | External event or pulse accumulate input | Capture TnCNT2 into TnCRB                   |
|     | TnAEN = X<br>TnBEN = 1 | External event or pulse accumulate input | External event if TnPTSE = 0         | Capture TnCNT1 into TnCRB and preset TnCNT1 | External event or pulse accumulate input | Capture TnCNT2 into TnCRB and preset TnCNT2 |

### 3.13.2.7 IO configuration linked to MFT timers

The MFT timers can be connected to the BlueNRG1 IO pins for the following features:

- Input signal to trig the timer in capture mode.
- Output signal when PWM mode is used (clock output emulation with controlled duty cycle)

In capture mode, the timer waits for an external IO event to start counting. The chosen IO for capture is programmed through IOSEL\_MFTX register in IO peripheral. This register allows configuring input capture IO for timers A and B of both MFT1 and MFT2, depending on which timer(s) are configured in capture mode.

In PWM mode, the signal is output on PWM0 IO for MFT1 and PWM1 for MFT2. Those IOs are available at different location thanks to alternate option. So to output the chosen PWM signal, it is necessary to configure the IO with the dedicated mode.

### 3.13.2.8 Timer interrupts

All sources have a pending flag associated with them, and can be enabled or disabled by software. The pending flags are named TnXPND, where n denotes the instance of the module, and X represents a letter from A to D. An interrupt enable flag (TnXIEN) is associated with each interrupt-pending flag. Interrupt sources A, B and C can each generate a timer interrupt MFT1A for MFT1 and MFT2A for MFT2, whereas interrupt source D can generate a timer interrupt MFT1B for MFT1 and MFT2B for MFT2. Not all interrupt sources are available in all modes. [Table 146: "MFT interrupt functions"](#) shows which events can trigger an interrupt in which mode of operation.

**Table 146: MFT interrupt functions**

| Sys. Int.                   | Interrupt pending flag | Mode 1                   | Mode 1a                  | Mode 2                          | Mode 3                   | Mode 4                          |
|-----------------------------|------------------------|--------------------------|--------------------------|---------------------------------|--------------------------|---------------------------------|
|                             |                        | PWM and counter          | PWM pulse train          | Dual-input capture and counter  | Dual independent counter | Input capture plus timer        |

## 3.14 Watchdog

### 3.14.1 Introduction

The watchdog timer provides a way of recovering from software crashes.

The watchdog monitors the interrupt and asserts a reset signal if the interrupt remains unserved for the entire programmed period.

The watchdog clock is used to generate a regular interrupt, depending on a programmed value. It is counting down at a fixed frequency around 32.768 kHz provided either by embedded RCO or by the external XO 32 kHz.

Main features are:

- 32-bit down counter at fixed frequency 32.768 kHz
- Generate an interrupt each time the counter reaches zero
- Generate an internal reset that reboot the system if the generated interrupt is not cleared by software and a second interrupt occurs

### 3.14.2 Functional description

The watchdog timer is a 32-bit down counter that divides the clock input to produce an interrupt. The divide ratio is fully programmable and controls the interrupt interval, which can be calculated as:

Interrupt interval = (WDT\_LOAD + 1) / (clock frequency in Hz).

The table below shows examples of WDT\_LOAD values.

**Table 157: Watchdog interrupt interval**

| WDT_LOAD   | Interrupt interval (ms) |
|------------|-------------------------|
| 4294967295 | 131072000               |
| 65535      | 2000                    |
| 32767      | 1000                    |
| 4095       | 125                     |
| 127        | 3.90625                 |
| 63         | 1.953125                |
| 1          | 0.0610                  |

A watchdog interrupt is generated each time the counter reaches zero. The counter is then reloaded with the content of the WDT\_LR register. The interrupt status should be cleared by writing to the interrupt clear register. When the interrupt is cleared, the counter is

reloaded with the WDT\_LOAD value. If the interrupt status is not cleared and a new interrupt is generated, then a watchdog Reset is generated, rebooting the system.

The watchdog interrupt and Reset generation can be enabled or disabled as required by the system using the relevant bits in the control register. When the interrupt generation is disabled the watchdog counter is also stopped, and when the interrupt is enabled the counter will start from the programmed value, not the last-count value.

Write access to the registers within the watchdog timer can be disabled in the watchdog lock register. Writing a value of 0x1ACC\_E551 to this WDT\_LOCK register allows write access to all other registers; writing any other value disables write access. This feature is included to allow some protection against software that might otherwise disable the watchdog functionality.

### 3.14.3 Watchdog registers

WDG peripheral base address (WDG\_BASE\_ADDR) 0x40700000.

**Table 158: WDG registers**

## 3.15 RTC

### 3.15.1 Introduction

The RTC timer can be used to provide an interrupt at regular time intervals. It generates an interrupt signal when it reaches zero after decrementing for a programmed number of cycles of the real-time clock input. The RTC timer can restart automatically from a load value when reaching zero if the auto restart mode is enabled, or it can stop when it reaches zero.

The RTC is clocked by the 32 kHz clock and is switched off in low-power modes which prevents this timer to be used for wake-up events.

### 3.15.2 Functional description

The RTC peripheral can be used either as real-time clock timer or as real-time clock watch.

#### 3.15.2.1 Real-time clock timer

The real-time clock timer (RTC timer) can be used to provide an interrupt at regular time intervals.

The RTC timer can restart automatically from a load value when reaching zero if the auto restart mode is enabled, or it can stop when it reaches zero.

The RTC timer has the following features:

- 32-bit down-counter.
- Interrupt generation when timer reaches zero.
- Start, auto restart (after counts to zero) and stop capability.
- On-the-fly register read and write access.
- 1/32 kHz minimum period.
- Multiple modes: periodic interrupt and single interrupt generation.
- Capability to switch between two load values in periodic mode. The timer reloads alternatively from one load value to the other and the down-counter starts decrementing every 31.25  $\mu$ s (on average).

The RTC timer is a 32-bit free-running counter, clocked by the 32 kHz clock signal (from an embedded 32 kHz RC), that works in two modes: periodic and one-shot.

**Table 166: RTC modes**

| RTTOS bit | Mode     | Description                                                                                                                                                                                                    |
|-----------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b        | Periodic | The counter generates an interrupt at a constant interval, reloading a load value after wrapping past zero. There are two load values: RTC_TLR1 for pattern value 0 and RTC_TLR2 for pattern value 1.          |
| 1b        | One-shot | The counter generates an interrupt once. When the counter reaches zero, it halts until the user restarts it by: setting bit RTTEN in the RTC_TCR register of writing a new value to the load register RTC_TLR1 |

The RTC timer load registers define the values from which the counter restarts alternatively.

In periodic mode, the timer must be stopped by the software before writing to a load register. The counter loads a value from RTC\_TLR1 or from RTC\_TLR2, depending on the value of the current pattern value that crosses the pattern register to decide after each interrupt generation, which value to load. The number of pattern bits to be crossed periodically (from the 128 bits) is specified in RTC\_TCR [10:4]. This process offers the possibility to have better precision of the average tick period.

In one-shot mode, the timer stops when it reaches zero, but the software can also stop it. Once the counter is halted, the load registers (RTC\_TLR1, RTC\_TLR2) can be written and the counter considers the new written value. After a write, RTTEN (RTC\_TCR) is set if the timer is in self-start mode.

Writing to RTC\_TLR1 or RTC\_TLR2 has no effect when the counter is running (the registers contents are not changed).

### 3.15.2.2 Real-time clock watch

The RTC clock watch consists of two counters and two alarm registers that have the following features:

- Two counters:
  - Counts seconds, minutes, hours, days of the week, days of the month.
  - Counts years.
- Two alarm registers:
  - To trigger an interrupt at exact date and time.

The clock watch counters are split in two registers:

The RTC\_CWDR register that holds:

- Seconds on six bits. Valid values are 0 to 59. (60, 61, 62 and 63 are invalid values, programming the RTC\_CWDR with these values leads to unpredictable behavior.) The seconds are incremented on the CLK1HZ clock rate.
- Minutes on six bits. Valid values are 0 to 59 (60, 61, 62 and 63 are invalid values, programming the RTC\_CWDR with these values leads to unpredictable behavior.)
- Hours on five bits. Valid values are 0 to 23 (24 to 31 are invalid values, programming the RTC\_CWDR with these values leads to unpredictable behavior.)

- The day of the week on three bits. Valid values are 1 (Sunday) to 7 (Saturday) (0 is an invalid value, programming the RTC\_CWDR with this value leads to unpredictable behavior.)
- The day of the month on five bits. Valid values are 1 to 31 for January, March, May, July, August, October and December, 1 to 30 for April, June, September, and November, 1 to 29 for February on leap years, or 1 to 28 for February on non-leap years. All other values are invalid values. Programming the RTC\_CWDR with these values leads to unpredictable behavior.)
- The month on four bits. Valid values are 1 (January) to 12 (December). 0, 13, 14 and 15 are invalid values, programming the RTC\_CWDR with these values leads to unpredictable behavior.

The RTC\_CWYR register holds:

- The year, from 0 to 4096

The clock watch time and date can be changed by writing new settings in the RTC\_CWDLR and RTC\_CWYLR load registers. The new setting is transferred to the clock watch counters on the next CLK1HZ rising edge after the RTC\_CWDLR register has been written.

After each increment of the clock watch counters, the RTC\_CWDR and RTC\_CWYR registers are compared to the clock watch match registers, RTC\_CWDMR and RTC\_CWYMR.

If both pairs of registers match, the internal interrupt signal RTCWINTR is raised.

To ignore the corresponding bit-field of the RTC\_CWDR register during the comparison, program the month (CWMONTHM), day of the month (CWDAYMM) or day of the week (CWDAYWM) bit-fields of the RTC\_CWDMR register with zero values.

To ignore the RTC\_CWYR register during the comparison, program the year bit-fields of RTC\_CWYMR register with zero values.

### 3.15.2.3 RTC interrupts

The RTC generates two internal interrupt signals:

- RTCINTR: raised when the two clock watch counter registers (RTC\_CWDR and RTC\_CWYR) match the two clock watch alarm registers (RTC\_CWDMR and RTC\_CWYMR). Some bit-fields can be 'don't care' during the comparison if a zero value is used for year, month, day of month and day of week. The software must clear this interrupt by writing 1 in the bit RTCCWIC of RTC\_ICR register.
- RTTINTR: raised when the full 32-bit down-counter RTC\_TDR reaches zero and is only cleared by writing 1 in the bit RTTIC of the RTC\_ICR register. The most significant carry bit of the counter detects the counter reaches zero. The software must clear this interrupt by writing 1 in the bit RTCTIC of the RTC\_ICR register.

Each individual interrupt can be masked by writing 0b to its corresponding interrupt mask set/clear bit in the RTC\_IMSC register. Both the raw interrupt status (prior to masking) and the final interrupt status (after masking) for each individual interrupt signal can be read from the RTC\_RIS and RTC\_MIS status registers.

The RTC delivers also a single combined interrupt signal, RTUINTR. This interrupt line is the logical OR of the both internal interrupt signals described above and is the signal connected to the processor interrupt line.

### 3.15.3 RTC registers

RTC peripheral base address (RTC\_BASE\_ADDR) 0x40F00000.

## 3.16 RNG

### 3.16.1 Introduction

The RNG is a real random number generator based on a continuous analog noise that provides a 16-bit value to the host when read.

### 3.16.2 Functional description

The peripheral is normally used by the Bluetooth Stack, but the user can read the random value at any time by accessing the register VAL. The RNG peripheral is addressed through the AHB, so the access must be at 32-bit, otherwise hard fault is generated on Cortex M0.

The minimum period between two consecutive random numbers is about 1.25  $\mu$ s.

### 3.16.3 RNG registers

RNG peripheral base address (RNG\_BASE\_ADDR) 0xB0000000

**Table 188: RNG registers**

### 3.17 PDM stream processor

The BlueNRG-1 integrates a digital filter for processing PDM stream coming from a digital microphone and inputting into a GPIO pin. The BlueNRG-1 outputs a 0.8MHz or 1.6MHz signal into a GPIO pin for providing the digital microphone with a frequency clock.

### 3.18 System timer (SysTick)

The BlueNRG-1 includes a system timer (SysTick) that can be polled by software or can be configured to generate an interrupt. SysTick interrupt has its own entry in the vector table and therefore can have its own handler.

### 3.19 Public key accelerator (PKA)

The Public key accelerator is for the computation of cryptographic public key primitives through elliptic curve cryptography (ECC) using a predefined prime modulus and a predefined curve.

#### 3.19.1 PKA functional description

The PKA core is clocked by the system clock divided by two and the PKA memory is clocked by system clock. This peripheral is addressed through the AHB, so the access must be at 32-bit or a hard fault is generated on the Cortex M0.

The PKA works on a 4 kB dedicated RAM block located in 0xC0000400.

The main features of the PKA block are:

- elliptic curve Diffie-Hellman (ECDH) public-private key pair calculation accelerator

- based on the Montgomery method for fast modular multiplications
- built-in Montgomery domain inward and outward transformations
- AMBA AHB lite slave interface with a reduced command set
- single port internal memory available for the system when the BlueNRG-1 PKA is not using it.

The PKA and the PKA RAM are clock gated by default after reset, so the clock must be enabled in CKGEN\_SOC before using PKA functionality.

The input data, output data and data verification result have specific locations in the PKA RAM.

**Table 192: PKA RAM data location**

| Parameter description                | PKA RAM offset address | Size (words)       |
|--------------------------------------|------------------------|--------------------|
| INPUT: ECC K value of kP             | 0x6C                   | EOS <sup>(1)</sup> |
| INPUT: input point P, coordinate X   | 0x90                   | EOS                |
| INPUT: input point P, coordinate Y   | 0xB4                   | EOS                |
| OUTPUT: output point P, coordinate X | 0x90                   | EOS                |
| OUTPUT: output point P, coordinate Y | 0xB4                   | EOS                |
| OUTPUT: error value                  | 0x00                   | 1                  |

**Notes:**

<sup>(1)</sup>ECC operand size.

An error value of 1 indicates that input point P does not satisfy the curve equation; in this case, the computation is very short. If the calculation returns an error value of 0, the result is valid.

The maximum length of data is calculated by:

$$\text{Max. EOS} = (\text{max\_ecc\_size} / \text{word\_size}) + 1$$

If ECC P256 is used, the PKA core needs an operand of 9 (256/32 + 1) words. When loading a 256-bit (8 word) input, an additional word is requested and must be filled with zero.

The starting point P for the computation is:

- **PX** = (0x6B17D1F2, 0xE12C4247, 0xF8BCE6E5, 0x63A440F2, 0x77037D81, 0x2DEB33A0, 0xF4A13945, 0xD898C296)
- **PY** = (0x4FE342E2, 0xFE1A7F9B, 0x8EE7EB4A, 0x7C0F9E16, 0x2BCE3357, 0x6B315ECE, 0xCBB64068, 0x37BF51F5)

### 3.19.2 PKA registers

PKA peripheral base address (PKA\_BASE\_ADDR) 0xC0000000

**Table 193: PKA registers**

| Address offset | Name | RW | Reset      | Description                 |
|----------------|------|----|------------|-----------------------------|
| 0x00           | CSR  | RW | 0x00000002 | Command and status register |
| 0x04           | ISR  | RW | 0x00000000 | Interrupt status register   |
| 0x08           | IEN  | RW | 0x00000000 | Interrupt enable register   |

Table 194: PKA – CSR register description: address offset PKA\_BASE\_ADDR+0x00

| Bit  | Field name | Reset | RW | Description                                                                                                                                                                                                                                        |

All RESERVED fields inside registers must always be written with their default value.

## 3.20 TX/RX event alert

The BlueNRG-1 is provided with the ANATEST1 (pin 14 for QFN32 package and pin D4 for WCSP34 package) signal which alerts forthcoming transmission or reception event. The ANATEST1 pin switches to high level about 18  $\mu$ s before transmission and about 10  $\mu$ s before reception. Then, it switches to low level at the end of the event. The signal can be used to control external antenna switching and to support coexistence with other wireless technologies.

## 3.21 SWD debug feature

The BlueNRG-1 embeds the ARM serial wire debug (SWD) port. It is two pins (clock and single bi-directional data) debug interface, providing all the debug functionality plus real-

time access to system memory without halting the processor or requiring any target resident code.

**Table 197: SWD port**

| Pin functionality | Pin name | Pin description  |
|-------------------|----------|------------------|
| SWCLK             | IO9      | SWD clock signal |
| SWDIO             | IO10     | SWD data signal  |

The Cortex-M0 subsystem of the BlueNRG-1 embeds two breakpoints and one watchpoint.

### 3.21.1 Debugging tips

There are certain situations where debug access is disabled and the chip cannot be accessed, including:

- application that disables debug pins
- application that set the device in sleep or standby state, in which the debug port is not powered.

These cases are common during application development and device can end up in a state where debug access is no longer possible. To recover this situation, it is recommended to force IO7 pin high and hardware reset the device in order to force execution of the updater code (see [Section 3.23: "Pre-programmed bootloader"](#)). The user can then connect with SWD interface and erase the device Flash memory.

## 3.22 Bluetooth low energy radio

The BlueNRG-1 integrates a RF transceiver compliant to the Bluetooth specification and to the standard national regulations in the unlicensed 2.4 GHz ISM band.

The RF transceiver requires very few external discrete components. It provides 96 dB link budgets with excellent link reliability, keeping the maximum peak current below 15 mA.

In transmit mode, the power amplifier (PA) drives the signal generated by the frequency synthesizer out to the antenna terminal through a very simple external network. The power delivered as well as the harmonic content depends on the external impedance seen by the PA.

### 3.22.1 Radio operating modes

Several operating modes are defined for the BlueNRG-1 radio:

- Reset mode
- Sleep mode
- Active mode
- Radio mode
  - RX mode
  - TX mode

In Reset mode, the BlueNRG-1 is in ultra-low power consumption: all voltage regulators, clocks and the RF interface are not powered. The BlueNRG-1 enters Reset mode by asserting the external Reset signal. As soon as it is de-asserted, the device follows the normal activation sequence to transit to active mode.

In sleep mode either the low speed crystal oscillator or the low speed ring oscillator are running, whereas the high speed oscillators are powered down as well as the RF interface. The state of the BlueNRG- is retained and the content of the RAM is preserved.

While in sleep mode, the BlueNRG- waits until an internal timer expires and then it goes into active mode.

In active mode the BlueNRG- is fully operational: all interfaces, including RF, are active as well as all internal power supplies together with the high speed frequency oscillator. The MCU core is also running.

Radio mode differs from active mode as also the RF transceiver is active and it is capable of either transmitting or receiving.

### 3.23 Pre-programmed bootloader

BlueNRG-1 device has a pre-programmed bootloader supporting UART protocol with automatic baudrate detection. Main features of the embedded bootloader are:

- Auto baudrate detection up to 460 kbps
- Flash mass erase, section erase
- Flash programming
- Flash readout protection enable/disable

The pre-programmed bootloader is an application which is stored on the BlueNRG-1 internal ROM at manufacturing time by STMicroelectronics. This application allows upgrading the device Flash with a user application using a serial communication channel (UART).

Bootloader is activated by hardware by forcing IO7 high during power-up or hardware Reset, otherwise, application residing in Flash will be launched.

The customer application must ensure that IO7 is forced low during power up. Bootloader protocol is described in a separate application note.

### 3.24 Unique device serial number

The BlueNRG-1 device has a unique six-byte serial number stored at address 0x100007F4: it is stored as two words (8 bytes) at addresses 0x100007F4 and 0x100007F8 with unique serial number padded with 0xAA55.

## 4 Pin description

The BlueNRG-1 is proposed in two package versions: WCSP34 offering 14 GPIOs and QFN32 offering 15 GPIOs. [Figure 21: "BlueNRG-1 pin-out top view \(QFN32\)"](#) shows the QFN32 pin out and [Figure 22: "BlueNRG-1 ball out top view \(WCSP34\)"](#) shows the WCSP34 ball out.

**Figure 21: BlueNRG-1 pin-out top view (QFN32)**

| Pins |    | Name      | I/O | Description                                          |
|------|----|-----------|-----|------------------------------------------------------|
| 16   | D5 | ADC2      | I   | ADC input 2                                          |
| 17   | A6 | FXTAL1    | I   | 16/32 MHz crystal                                    |
| 18   | B5 | FXTAL0    | I   | 16/32 MHz crystal                                    |
| 19   | -  | VBAT2     | VDD | Battery voltage input                                |
| 20   | C6 | RF1       | I/O | Antenna + matching circuit connection                |
| 21   | D6 | RF0       | I/O | Antenna + matching circuit connection                |
| 22   | E4 | SXTAL1    | I   | 32 kHz crystal                                       |
| 23   | E5 | SXTAL0    | I   | 32 kHz crystal                                       |
| 24   | E6 | VBAT1     | VDD | Battery voltage input                                |
| 25   | B3 | RESETN    | I   | System reset                                         |
| 26   | F6 | SMPSFILT1 | I   | SMPS output to external filter                       |
| 27   | F4 | SMPSFILT2 | I/O | SMPS output to external filter/battery voltage input |
| 28   | F3 | VDD1V2    | O   | 1.2 V digital core output                            |
| 29   | -  | IO13      | I/O | General purpose digital Input                        |
| 30   | F2 | IO12      | I/O | General purpose digital Input                        |
| 31   | E3 | TEST      | I   | Test pin put to GND                                  |
| 32   | E2 | IO11      | I/O | General purpose digital I/O                          |
| -    | A4 | GND       | GND | Ground                                               |
| -    | B6 | GND       | GND | Ground                                               |
| -    | C1 | GND       | GND | Ground                                               |
| -    | F5 | GND       | GND | Ground                                               |

**Notes:**

<sup>(1)</sup>The pin IO7/BOOT is monitored by bootloader after power up or hardware Reset and it should be low to prevent unwanted bootloader activation.

<sup>(2)</sup>Pins used for the crystal startup measurement.

## 5 Memory mapping

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and highest numbered byte the most significant.

The addressable memory space is divided into 16 main blocks, each 256 MB. All the memory areas that are not allocated to on-chip memories and peripherals are considered "RESERVED".

For the detailed mapping of an available memory and register areas, please refer to the memory map in table below and to the register lists detailed in each of the peripheral sections.

**Table 199: Memory mapping**

| Address                   | Cortex-M0 address map | Size   | Description         |
|---------------------------|-----------------------|--------|---------------------|
| 0x0000_0000 – 0x0000_0FFF | Code                  | 4 kB   | ROM                 |
| 0x1000_0000 – 0x1000_0FFF | Code                  | 4 kB   | ROM                 |
| 0x1004_0000 – 0x1006_7FFF | Code                  | 160 kB | Flash               |
| 0x2000_0000 – 0x2000_2FFF | SRAM0 always on       | 12 kB  | SRAM                |
| 0x2000_3000 – 0x2000_5FFF | SRAM1 switchable      | 12 kB  | SRAM                |
| 0x2000_6000 – 0x3FFF_FFFF |                       |        | RESERVED            |
| 0x4000_0000               | APB peripheral        | 4 kB   | GPIO                |

| 0xE010_0000 – 0xEFFF_FFFF | RESERVED               | 256 MB | RESERVED            |
| 0xF000_0000 – 0xFFFF_FFFF |                        | 256 MB | RESERVED            |

**Notes:**

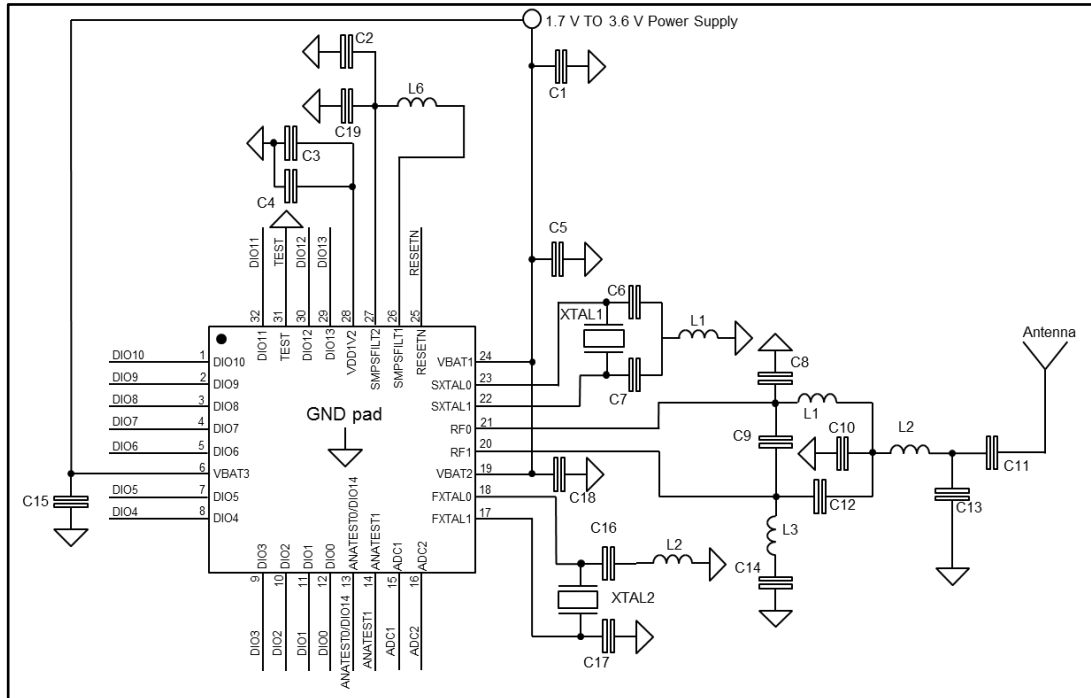

<sup>(1)</sup>The I<sup>2</sup>C 1 is not available in WLCSP34 package.

All the peripherals are addressed by APB, except DMA, RNG and PKA peripherals that are addressed by AHB. The peripherals DMA, RNG and PKA that are addressed through the AHB, must be accessed only with 32-bit accesses. Any 8-bit or 16-bit access generates an AHB error leading to a hard fault on Cortex-M0.

## 6 Application circuit

The schematics below are purely indicative.

**Figure 24: Application circuit: active DC-DC converter QFN32 package**

**Figure 25: Application circuit: non-active DC-DC converter QFN32 package**

Figure 27: Application circuit: non active DC-DC converter WCSP34 package

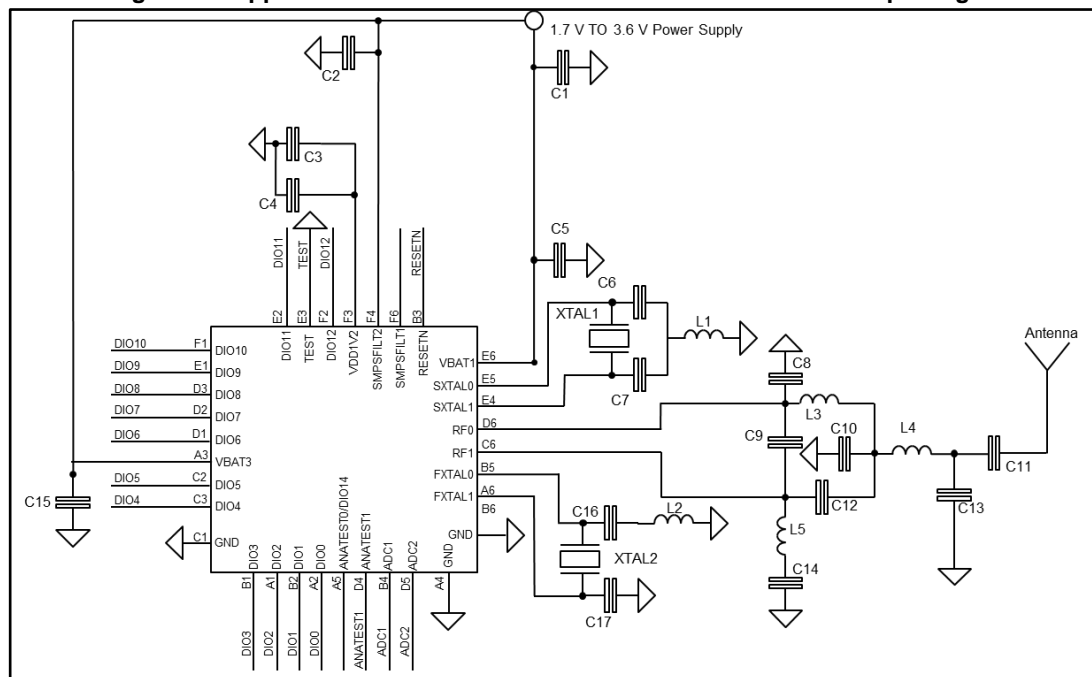

Table 200: External component list

| Component | Description                                      |
|-----------|--------------------------------------------------|
| C1        | Decoupling capacitor                             |
| C2        | DC-DC converter output capacitor                 |
| C3        | Decoupling capacitor for 1.2 V digital regulator |
| C4        | Decoupling capacitor for 1.2 V digital regulator |
| C5        | Decoupling capacitor                             |
| C6        | 32 kHz crystal loading capacitor                 |
| C7        | 32 kHz crystal loading capacitor                 |
| C8        | RF balun/matching network capacitor              |
| C9        | RF balun/matching network capacitor              |
| C10       | RF balun/matching network capacitor              |
| C11       | RF balun/matching network capacitor              |
| C12       | RF balun/matching network capacitor              |
| C13       | RF balun/matching network capacitor              |
| C14       | RF balun/matching network capacitor              |
| C15       | Decoupling capacitor                             |
| C16       | 16/32 MHz crystal loading capacitor              |
| C17       | 16/32 MHz crystal loading capacitor              |
| C18       | Decoupling capacitor                             |
| C19       | DC-DC converter output capacitor                 |
| L1        | 32 kHz crystal filter inductor                   |
| L2        | 16/32 MHz crystal filter inductor                |
| L3        | RF balun/matching network inductor               |
| L4        | RF balun/matching network inductor               |
| L5        | RF balun/matching network inductor               |
| XTAL1     | 32 kHz crystal (optional)                        |
| XTAL2     | 16/32 MHz crystal                                |

## 7 Absolute maximum ratings and thermal data

Table 201: Absolute maximum ratings

| Pin                                               | Parameter                                       | Value        | Unit |
|---------------------------------------------------|-------------------------------------------------|--------------|------|
| VBAT3, VBAT2, VBAT1, RESETN, SMPSFILT1, SMPSFILT2 | DC-DC converter supply voltage input and output | -0.3 to +3.9 | V    |
| VDD1V2                                            | DC voltage on linear voltage regulator          | -0.3 to +3.9 | V    |
| DIO0 to DIO14, TEST                               | DC voltage on digital input/output pins         | -0.3 to +3.9 | V    |
| ANATEST0, ANATEST1, ADC1, ADC2                    | DC voltage on analog pins                       | -0.3 to +3.9 | V    |
| FXTAL0, FXTAL1, SXTAL0, SXTAL1                    | DC voltage on XTAL pins                         | -0.3 to +1.4 | V    |
| RF0, RF1                                          | DC voltage on RF pins                           | -0.3 to +1.4 | V    |
| TSTG                                              | Storage temperature range                       | -40 to +125  | °C   |
| VESD-HBM                                          | Electrostatic discharge voltage                 | ±2.0         | kV   |

Absolute maximum ratings are those values above which damage to the device may occur. Functional operation under these conditions is not implied. All voltages are referred to GND.

Table 202: Thermal data

| Symbol   | Parameter                           | Value                       | Unit |
|----------|-------------------------------------|-----------------------------|------|
| Rthj-amb | Thermal resistance junction-ambient | 34 (QFN32)<br>50 (WLCSP34)  | °C/W |
| Rthj-c   | Thermal resistance junction-case    | 2.5 (QFN32)<br>25 (WLCSP34) | °C/W |

## 8 General characteristics

**Table 203: Recommended operating conditions**

| Symbol         | Parameter                           | Min. | Typ. | Max. | Unit |
|----------------|-------------------------------------|------|------|------|------|
| VBAT           | Operating battery supply voltage    | 1.7  |      | 3.6  | V    |
| T <sub>A</sub> | Operating ambient temperature range | -40  |      | +105 | °C   |

## 9 Electrical specifications

### 9.1 Electrical characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ . All performance data are referred to a  $50\text{ }\Omega$  antenna connector, via reference design, QFN32 package version.

**Table 204: Electrical characteristics**

| Symbol                                            | Parameter      | Test conditions                                | Min. | Typ. | Max. | Unit |
|---------------------------------------------------|----------------|------------------------------------------------|------|------|------|------|
| Power consumption when DC-DC converter active     |                |                                                |      |      |      |      |
| I <sub>BAT</sub>                                  | Supply current | Reset                                          | –    | 5    | –    | nA   |
|                                                   |                | Standby                                        | –    | 500  | –    | nA   |
|                                                   |                | Sleep mode: 32 kHz XO ON (24 KB retention RAM) | –    | 0.9  | –    | μA   |
|                                                   |                | Sleep mode: 32 kHz RO ON (24 KB retention RAM) |      | 2.1  |      |      |
|                                                   |                | Active mode: CPU, Flash and RAM on             | –    | 1.9  | –    | mA   |
|                                                   |                | RX                                             | –    | 7.7  | –    | mA   |
|                                                   |                | TX +8 dBm                                      | –    | 15.1 | –    | mA   |
|                                                   |                | TX +4 dBm                                      |      | 10.9 |      |      |
|                                                   |                | TX +2 dBm                                      |      | 9    |      |      |
|                                                   |                | TX -2 dBm                                      |      | 8.3  |      |      |

### 9.1.1 Peripheral current consumption

Table 206: Peripheral current consumption

| Peripheral        | Typical consumption<br>V <sub>DD</sub> = 3.0 V, T <sub>A</sub> = 25 °C | Unit |
|-------------------|------------------------------------------------------------------------|------|
| GPIO              | 11.6                                                                   | μA   |
| Flash controller  | 6.3                                                                    |      |
| System controller | 0.2                                                                    |      |
| UART              | 82.3                                                                   |      |
| SPI               | 46.5                                                                   |      |
| Watchdog          | 3.6                                                                    |      |
| ADC               | 6.3                                                                    |      |
| I2C1              | 95.9                                                                   |      |
| I2C2              | 97.1                                                                   |      |
| MFT1              | 5.4                                                                    |      |
| MFT2              | 6.2                                                                    |      |
| RTC               | 7.5                                                                    |      |
| DMA               | 16.3                                                                   |      |
| RNC               | 21.7                                                                   |      |
| PKA               | 23.7                                                                   |      |

The values are calculated as the increment to the current consumption when the peripheral is activated. The peripheral is activated if the related clock is provided.

## 9.2 RF general characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ . All performance data are referred to a  $50\text{ }\Omega$  antenna connector, via reference design, QFN32 package version.

Table 207: RF general characteristics

| Symbol | Parameter                   | Test conditions | Min. | Typ. | Max.   | Unit |
|--------|-----------------------------|-----------------|------|------|--------|------|
| FREQ   | Frequency range             |                 | 2400 | –    | 2483.5 | MHz  |
| FCH    | Channel spacing             |                 | –    | 2    | –      | MHz  |
| RFch   | RF channel center frequency |                 | 2402 | –    | 2480   | MHz  |

## 9.3 RF transmitter characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ . All performance data are referred to a  $50\text{ }\Omega$  antenna connector, via reference design, QFN32 package version.

Table 208: RF transmitter characteristics

| Symbol | Parameter                                              | Test conditions                                            | Min. | Typ.                        | Max. | Unit     |

### 9.5.1 High speed crystal oscillator

The BlueNRG includes a fully integrated low power 16/32 MHz Xtal oscillator with an embedded amplitude regulation loop. In order to achieve low power operation and good frequency stability of the XTAL oscillator, certain considerations with respect to the quartz load capacitance  $C_0$  need to be taken into account. [Figure 28: "High speed oscillator block diagram"](#) shows a simplified block diagram of the amplitude regulated oscillator used on the BlueNRG-1.

Figure 28: High speed oscillator block diagram

Low power consumption and fast startup time is achieved by choosing a quartz crystal with a low load capacitance  $C_0$ . A reasonable choice for capacitor  $C_0$  is 12 pF. To achieve good frequency stability, the following equation needs to be satisfied:

$$C_0 = \frac{C'_1 * C'_2}{C_1 + C_2}$$

Where  $C'_1 = C_1 + C_{PCB1} + C_{PAD}$ ,  $C'_2 = C_2 + C_{PCB2} + C_{PAD}$ , where  $C_1$  and  $C_2$  are external (SMD) components,  $C_{PCB1}$  and  $C_{PCB2}$  are PCB routing parasites and  $C_{PAD}$  is the equivalent small-signal pad-capacitance. The value of  $C_{PAD}$  is around 0.5 pF for each pad. The routing parasites should be minimized by placing quartz and  $C_1/C_2$  capacitors close to the chip, not

only for an easier matching of the load capacitance  $C_0$ , but also to ensure robustness against noise injection. Connect each capacitor of the Xtal oscillator to ground by a separate vias.

## 9.6 Low speed crystal oscillator characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ .

Table 211: Low speed crystal oscillator characteristics

| Symbol           | Parameter                    | Test conditions                                                                                                       | Min. | Typ.   | Max. | Unit |
|------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------|------|--------|------|------|
| f <sub>NOM</sub> | Nominal frequency            |                                                                                                                       | –    | 32.768 | –    | kHz  |
| f <sub>TOL</sub> | Frequency tolerance          | Includes initial accuracy, stability over temperature, aging and frequency pulling due to incorrect load capacitance. | –    | –      | ±50  | ppm  |
| ESR              | Equivalent series resistance |                                                                                                                       | –    | –      | 90   | kΩ   |
| PD               | Drive level                  |                                                                                                                       | –    | –      | 0.1  | μW   |

These values are the correct ones for NX3215SA-32.768 kHz-EXS00A-MU00003.

## 9.7 High speed ring oscillator characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ .

Table 212: High speed ring oscillator characteristics

| Symbol           | Parameter         | Test conditions | Min. | Typ. | Max. | Unit |
|------------------|-------------------|-----------------|------|------|------|------|
| f <sub>NOM</sub> | Nominal frequency |                 | –    | 14   | –    | MHz  |

## 9.8 Low speed ring oscillator characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ , QFN32 package version.

Table 213: Low speed ring oscillator characteristics

| Symbol                          | Parameter           | Test conditions | Min. | Typ. | Max. | Unit |
|---------------------------------|---------------------|-----------------|------|------|------|------|
| 32 kHz ring oscillator (LSROSC) |                     |                 |      |      |      |      |
| f <sub>NOM</sub>                | Nominal frequency   |                 | –    | 32   | –    | kHz  |
| f <sub>TOL</sub>                | Frequency tolerance |                 | –    | –    | ±500 | ppm  |

## 9.9 N-fractional frequency synthesizer characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical value are referred to  $T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ ,  $f_c = 2440\text{ MHz}$ .

Table 214: N-Fractional frequency synthesizer characteristics

| Symbol   | Parameter              | Test conditions                    | Min. | Typ. | Max. | Unit    |
|----------|------------------------|------------------------------------|------|------|------|---------|
| PNSYNTH  | RF carrier phase noise | At $\pm 1$ MHz offset from carrier | –    | -113 | –    | dBc/Hz  |
|          |                        | At $\pm 3$ MHz offset from carrier | –    | -119 | –    | dBc/Hz  |
| LOCKTIME | PLL lock time          |                                    | –    | –    | 40   | $\mu$ s |
| TOTIME   | PLL turn-on / hop time | Including calibration              | –    | –    | 150  | $\mu$ s |

## 9.10 Auxiliary block characteristics

Characteristics measured over recommended operating conditions unless otherwise specified. Typical values are referenced to  $T_A = 25^\circ\text{C}$ ,  $V_{BAT} = 3.0\text{ V}$ ,  $f_{\text{ADCclk}} = 1\text{ MHz}$ . QFN32 package version.

Table 215: Auxiliary block characteristics

| Symbol                            | Parameter                | Test conditions                                                                                                                                                                                                                        | Min.   | Typ. | Max.                                             | Unit |

## 10 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: **[www.st.com](http://www.st.com)**. ECOPACK® is an ST trademark.

## 10.1 QFN32 package information

Figure 29: QFN32 (5 x 5 x 1 pitch 0.5 mm) package outline

Table 216: QFN32 (5 x 5 x 1 pitch 0.5 mm) mechanical data

| Dim.   | mm       |      |      |
|--------|----------|------|------|
|        | Min.     | Typ. | Max. |
| A      | 0.80     | 0.85 | 1.00 |
| A1     | 0        | 0.02 | 0.05 |
| A3     | 0.20 REF |      |      |
| b      | 0.25     | 0.25 | 0.30 |
| D      | 5.00 BSC |      |      |

## 10.2 WLCSP34 package information

Figure 31: WLCSP34 (2.66 x 2.56 x 0.5 pitch 0.4 mm) package outline

1. The corner of terminal A1 must be identified on the top surface by using a laser marking dot.

Table 217: WLCSP34 (2.66 x 2.56 x 0.5 pitch 0.4 mm) mechanical data

| Dim. | mm.  |      |      | Notes |
|------|------|------|------|-------|
|      | Min. | Typ. | Max. |       |
| A    |      |      | 0.50 |       |
| A1   |      | 0.20 |      |       |
| b    |      | 0.27 |      | (1)   |
| D    | 2.50 | 2.56 | 2.58 | (2)   |
| D1   |      | 2.00 |      |       |
| E    | 2.60 | 2.66 | 2.68 | (3)   |
| E1   |      | 2.00 |      |       |
| e    |      | 0.40 |      |       |
| f    |      | 0.28 |      |       |
| g    |      | 0.33 |      |       |
| ccc  |      |      | 0.05 |       |

**Notes:**

(1) The typical ball diameter before mounting is 0.25 mm.

(2)  $D = f + D1 + f$ .

(3)  $E = g + E1 + g$ .

## 11 PCB assembly guidelines

For Flip Chip mounting on the PCB, STMicroelectronics recommends the use of a solder stencil aperture of 330 x 330  $\mu\text{m}$  maximum and a typical stencil thickness of 125  $\mu\text{m}$ .

Flip Chips are fully compatible with the use of near eutectic 95.8% Sn, 3.5% Ag, 0.7% Cu solder paste with no-clean flux. ST's recommendations for Flip-Chip board mounting are illustrated on the soldering reflow profile shown in [Figure 32: "Flip Chip CSP \(2.71 x 2.58 x 0.5 pitch 0.4 mm\) package reflow profile recommendation"](#).

**Figure 32: Flip Chip CSP (2.71 x 2.58 x 0.5 pitch 0.4 mm) package reflow profile recommendation**

**Table 218: Flip Chip CSP (2.71 x 2.58 x 0.5 pitch 0.4 mm) package reflow profile recommendation**

| Profile                                       | Value         |         |
|-----------------------------------------------|---------------|---------|
|                                               | Typ.          | Max.    |
| Temp. gradient in preheat (T = 70 - 180 °C/s) | 0.9 °C/s      | 3 °C/s  |
| Temp. gradient (T = 200 - 225 °C)             | 2 °C/s        | 3 °C/s  |
| Peak temp. in reflow                          | 240 - 245 °C  | 260 °C  |
| Time above 200 °C                             | 60 s          | 90 s    |
| Temp. gradient in cooling                     | -2 to -3 °C   | -6 °C/s |
| Time from 50 to 220 °C                        | 160 to 220 °C |         |

Dwell time in the soldering zone (with temperature higher than 220 °C) has to be kept as short as possible to prevent component and substrate damage. Peak temperature must not exceed 260 °C. Controlled atmosphere (N<sub>2</sub> or N<sub>2</sub>H<sub>2</sub>) is recommended during the whole reflow, especially above 150 °C.

Flip Chips are able to withstand three times the previous recommended reflow profile to be compatible with a double reflow when SMDs are mounted on both sides of the PCB plus one additional repair.

A maximum of three soldering reflows are allowed for these lead-free packages (with repair step included).

The use of a no-clean paste is highly recommended to avoid any cleaning operation. To prevent any bump cracks, ultrasonic cleaning methods are not recommended.

## 11.1 Ordering information

Table 219: Ordering information

| Order code  | Package        | Packing       |
|-------------|----------------|---------------|
| BlueNRG-132 | QFN32 (5x5 mm) | Tape and reel |
| BlueNRG-134 | WLCSP34        |               |

## 12 Revision history

Table 220: Document revision history

| Date        | Version | Changes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
