

NCP1361, NCP1366

Low Power Offline Constant Current PWM Current-Mode Controller with/without High Voltage Startup Current Source

The NCP1361/66 offers a new solution targeting output power levels from a few watts up to 20 W in a universal-mains flyback application. Due to a novel method this new controller offers a primary-side constant current control, saving secondary-side components to perform current regulation.

The NCP1361/66 operates in valley-lockout quasi-resonant peak current mode control mode at nominal load to provide high efficiency. When the secondary-side power starts diminishing, the switching frequency naturally increases until a voltage-controlled oscillator (VCO) takes the lead, synchronizing the MOSFET turn-on in a drain-source voltage valley. The frequency is thus reduced by stepping into successive valleys until the number 4 is reached. Beyond this point, the frequency is linearly decreased in valley-switching mode until a minimum is hit. Valley lockout during the first four drain-source valleys prevents erratic discrete jumps and provides good efficiency in lighter load situations.

Features

- $\pm 10\%$ Current Regulation
- 560 V Startup Current Source
- No Frequency Clamp, 80 or 110 kHz Maximum Switching Frequency Options
- Quasi-Resonant Operation with Valley Switching Operation
- Fixed Peak Current & Deep Frequency Foldback @ Light Load Operation.
- External Constant Voltage Feedback Adjustment
- Cycle by Cycle Peak Current Limit
- Built-In Soft-Start
- Over & Under Output Voltage Protection
- Wide Operation V_{CC} Range (up to 28 V)
- Low Start-up Current (2.5 μ A typ.) with NCP1361

ORDERING INFORMATION

See detailed ordering and shipping information on page 25 of this data sheet.

- Clamped Gate-drive Output for MOSFET
- CS & V_s/ZCD pin Short and Open Protection
- Internal Temperature Shutdown
- Less than 30 mW No-Load Performance at High Line with NCP1366 Version
- These are Pb-Free Devices

Typical Applications

- Low power ac-dc Adapters for Chargers
- Ac-dc USB chargers for Cell Phones, Tablets and Cameras

PIN FUNCTION DESCRIPTION

Pin out NCP1366	Pin out NCP1361	Name	Function
1	6	V _s /ZCD	Connected to the auxiliary winding; this pin senses the voltage output for the primary regulation and detects the core reset event for the Quasi-Resonant mode of operation.
2	5	FB	This pin connects to an optocoupler collector and adjusts the peak current setpoint.
3	4	CS	This pin monitors the primary peak current.
4	3	DRV	Controller switch driver.
5	2	GND	Ground reference.
6	1	V _{CC}	This pin is connected to an external auxiliary voltage and supplies the controller.
7	-	NC	Not Connected for creepage distance between high and low Voltage pins
8	-	HV	Connected the high-voltage rail, this pin injects a constant current into the V _{CC} capacitor for starting-up the power supply.

MAXIMUM RATINGS

Symbol	Rating	Value	Unit
V _{CC(MAX)}	Maximum Power Supply voltage, VCC pin, continuous voltage	-0.3 to 28	V
ΔV _{CC} /Δt	Maximum slew rate on V _{CC} pin during startup phase	+0.4	V/μs
V _{DRV(MAX)} I _{DRV(MAX)}	Maximum driver pin voltage, DRV pin, continuous voltage Maximum current for DRV pin	-0.3, V _{DRV} (Note 1) -300, +500	V mA
V _{MAX} I _{MAX}	Maximum voltage on low power pins (except pins DRV and VCC) Current range for low power pins (except pins DRV and VCC)	-0.3, 5.5 -2, +5	V mA
V _{HV}	High Voltage pin voltage	-0.3 to 560	V
R _{θJ-A}	Thermal Resistance Junction-to-Air	200	°C/W
T _{J(MAX)}	Maximum Junction Temperature	150	°C
	Operating Temperature Range	-40 to +125	°C
	Storage Temperature Range	-60 to +150	°C
	Human Body Model ESD Capability per JEDEC JESD22-A114F	2	kV
	Machine Model ESD Capability (All pins except DRV) per JEDEC JESD22-A115C	200	V
	Charged-Device Model ESD Capability per JEDEC JESD22-C101E	500	V

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. V_{DRV} is the DRV clamp voltage V_{DRV(high)} when V_{CC} is higher than V_{DRV(high)}. V_{DRV} is V_{CC} otherwise
2. This device contains latch-up protection and exceeds 100 mA per JEDEC Standard JESD78.

NCP1361, NCP1366

ELECTRICAL CHARACTERISTICS: ($V_{CC} = 12\text{ V}$, $C_{DRV} = 1\text{ nF}$, For typical values $T_J = 25^\circ\text{C}$, for min/max values $T_J = -40^\circ\text{C}$ to $+125^\circ\text{C}$, Max $T_J = 150^\circ\text{C}$, unless otherwise noted)

Characteristics	Conditions	Symbol	Min	Typ	Max	Unit
-----------------	------------	--------	-----	-----	-----	------

HIGH VOLTAGE STARTUP SECTION (NCP1366 only)

Startup current sourced by V_{CC} pin	$V_{HV} = 100\text{ V}$	I_{HV}	70	100	150	μA
Leakage current at HV	$V_{HV} = 400\text{ V}$, all options except NCP1366AABAY and NCP1366BABAY All other options	I_{HV_LKG}	–	0.1	1.0	μA
Minimum Start-up HV voltage	$I_{HV} = 95\%$ of $I_{HV}@V_{HV} = 100\text{ V}$, $V_{CC} = V_{CC(ON)} - 0.2\text{ V}$	$V_{HV(min)}$	–	22	25	V

SUPPLY SECTION AND V_{CC} MANAGEMENT

V_{CC} level at which driving pulses are authorized	V_{CC} increasing	$V_{CC(ON)}$	16	18	20	V
V_{CC} level at which driving pulses are stopped	V_{CC} decreasing	$V_{CC(OFF)}$	6.0	6.5	7.0	V
Internal Latch / Logic Reset Level V_{CC} clamp level		$V_{CC(RESET)}$	–	5.6	–	V
V_{CC} clamp level (A & C version)	Activated after Latch protection @ $I_{CC} = 100\ \mu\text{A}$	$V_{CC(CLAMP)}$	–	4.2	–	V
Minimal current into V_{CC} pin that keeps the controller Latched (NCP1366, A & C fault mode version)		$I_{CC(CLAMP)}$	–	–	20	μA
Minimal current into V_{CC} pin that keeps the controller Latched (NCP1361, A & C fault mode version)		$I_{CC(CLAMP)}$	–	–	6	μA
Current-limit resistor in series with the latch SCR		R_{LIM}	–	7	–	$\text{k}\Omega$
Over Voltage Protection	Over Voltage threshold	$V_{CC(OVP)}$	24	26	28	V
Start-up supply current, controller disabled or latched (Only valid with NCP1361)	$V_{CC} < V_{CC(ON)}$ & V_{CC} increasing from 0 V	I_{CC1}	–	2.5	5.0	μA
Internal IC consumption, steady state	$F_{sw} = 65\text{ kHz}$, $C_{DRV} = 1\text{ nF}$	I_{CC2}	–	1.7	2.5	mA
Internal IC consumption, frequency foldback mode	VCO mode, $F_{sw} = 1\text{ kHz}$, $C_{DRV} = 1\text{ nF}$	I_{CC3}	–	0.8	1.2	mA
Internal IC consumption when STBY mode is activated	VCO mode, $F_{sw} = f_{VCO(min)}$, $V_{Comp} = \text{GND}$, $C_{DRV} = 1\text{ nF}$ $f_{VCO(min)} = 200\text{ Hz}$, (options NCP1366AABAY, NCP1366BABAY, NCP1361AABAY, NCP1361BABAY and NCP1361EABAY) $f_{VCO(min)} = 200\text{ Hz}$, all other options $f_{VCO(min)} = 600\text{ Hz}$ $f_{VCO(min)} = 1.2\text{ kHz}$	I_{CC4}	–	200	250	μA

APPLICATION INFORMATION

The NCP1366/61 is a flyback power supply controller providing a means to implement primary side constant-current regulation. This technique does not need a secondary side feedback circuitry, associated bias current and an opto-coupler. NCP1366/61 implements a current-mode architecture operating in quasi-resonant mode. The controller prevents valley-jumping instability and steadily locks out in a selected valley as the power demand goes down. As long as the controller is able to detect a valley, the new cycle or the following drive remains in a valley. Due to a dedicated valley detection circuitry operating at any line and load conditions, the power supply efficiency will always be optimized. In order to prevent any high switching frequency two frequency clamp options are available.

- Quasi-Resonance Current-mode operation:** implementing quasi-resonance operation in peak current-mode control optimizes the efficiency by switching in the valley of the MOSFET drain-source voltage. Due to a proprietary circuitry, the controller locks-out in a selected valley and remains locked until the input voltage significantly changes. Only the four first valleys could be locked out. When the load current diminishes, valley switching mode of operation is kept but without valley lock-out. Valley-switching operation across the entire input/output conditions brings efficiency improvement and lets the designer build higher-density converters.
- Frequency Clamp:** As the frequency is not fixed and dependent on the line, load and transformer specifications, it is important to prevent switching frequency runaway for applications requiring maximum switching frequencies up to 90 kHz or 130 kHz. Two frequency clamp options at 80 kHz or 110 kHz are available for this purpose. In case frequency clamp is not needed, a specific version of the 1361/66 exists in which the clamp is deactivated.
- Primary Side Constant Current Regulation:** Battery charging applications request constant current regulation. NCP1361/66 controls and regulates the output current at a constant level regardless of the input and output voltage conditions. This function offers tight over power protection by estimating and limiting the maximum output current from the primary side, without any particular sensor.
- Optocoupler-based feedback:** the voltage feedback loop is classically implemented with an optocoupler and a NCP431 voltage reference in the secondary side. By pulling the feedback pin low, the controller adjusts the peak current setpoint and regulates V_{out} .

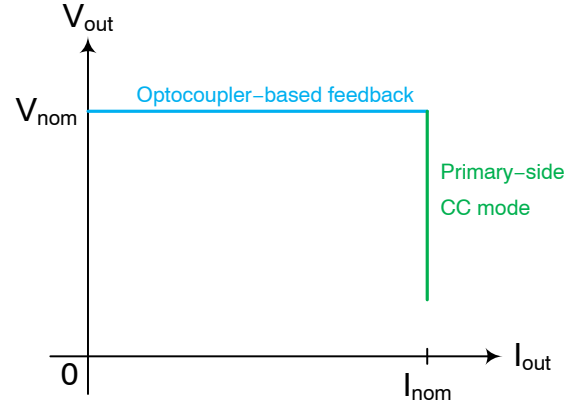

Figure 39. Constant-Voltage & Constant-Current Mode

- Soft-Start:** 4 ms internal fixed soft start guarantees a peak current starting from zero to its nominal value with smooth transition in order to prevent any overstress on the power components at each startup.
- Cycle-by-Cycle peak current limit:** If the max peak current reaches the V_{ILIM} level, the over current protection timer is enabled and starts counting. If the overload lasts T_{OCP} delay, then the fault is latched and the controller stops immediately driving the power MOSFET. The controller enters in a double hiccup mode before autorecovering with a new startup cycle.
- V_{CC} Over Voltage Protection:** If the V_{CC} voltage reaches the $V_{CC(OVP)}$ threshold the controller enters in latch mode. Thus it stops driving pulse on DRV pin:
 - A & C version – (Latched $V_{CC(OVP)}$):** V_{CC} capacitor is internally discharged to the $V_{CC(Clamp)}$ level with a very low power consumption: the controller is completely disabled. Resuming operation is possible by unplugging the line in order to releasing the internal V_{CC} thyristor with a V_{CC} current lower than the $I_{CC(Clamp)}$.
 - B version – (Autorecovery):** it enters in double hiccup mode before resuming operation.
- Winding Short-Circuit Protection:** An additional comparator senses the CS signal and stops the controller if V_{CS} reaches $V_{ILIM}+50\%$ (after a reduced LEB: t_{LEB2}). Short circuit protection is enabled only if 4 consecutive pulses reach SCP level. This small counter prevents any false triggering of short circuit protection during surge test for instance. This fault is latched and operations will be resumed like in a case of V_{CC} Over Voltage Protection.

- V_{out} Over Voltage Protection:** if the internally–built output voltage becomes higher than V_{OVP} level ($V_{ref_CV1} + 26\%$) a fault is detected.
 - A & C version:** This fault is latched and operations are resumed like in the **V_{CC} Over Voltage Protection** case.
 - B version:** the part enters in double hiccup mode before resuming operations.
- V_{out} Under Voltage Protection:** After each circuit power on sequence, V_{out} UVP detection is enabled only after the startup timer T_{EN_UVP} . This timer ensures that the power supply is able to fuel the output capacitor before checking the output voltage in on target. After this startup blanking time, UVP detection is enabled and monitors the Output voltage level. When the power supply is running in constant–current mode and when the output voltage falls below V_{UVP} level, the controller stops sending drive pulses and enters a double hiccup mode before resuming operations (A & B version), or latches off (C version).
- V_s/ZCD Pin Short Protection:** at the beginning of each off–time period, the V_s/ZCD pin is tested to check whether it is shorted or left open. In case a fault is detected, the controller enters in a double hiccup mode before resuming operations.
- Temperature Shutdown:** if the junction temperature reaches the T_{SHTDN} level, the controller stop driving the

power mosfet until the junction temperature decreases by $T_{SHTDN(HYS)}$, then the operation is resumed after a double hiccup mode.

Startup Operation

The high–voltage startup current source is connected to the bulk capacitor via the *HV* pin, it charges the V_{CC} capacitor. During startup phase, it delivers 100 μ A to fuel the V_{CC} capacitor. When V_{CC} pin reaches $V_{CC(on)}$ level, the NCP1361/66 is enabled. Before sending the first drive pulse to the power MOSFET, the *CS* pin has been tested for an open or shorted situation. If *CS* pin is properly wired, then the controller sends the first drive pulse to the power MOSFET. After sending these first pulses, the controller checks the correct V_s/ZCD pin wiring. Considering the V_s/ZCD pin properly wired, the controller engages a softstart sequence. The softstart sequence controls the max peak current from the minimal frozen primary peak current ($V_{CS(VCO)} = 120$ mV: 15% of V_{LLIM}) to the nominal pulse width by smoothly increasing the level.

Figure 40 illustrates a standard connection of the *HV* pin to the bulk capacitor. If the controller is in a latched fault mode (ex V_{CC_OVP} has been detected), the power supply will resume the operation after unplugging the converter from the ac line outlet. Due the extremely low controller consumption in latched mode, the release of the latch could be very long. The unplug duration for releasing the latch will be dependent on the bulk capacitor size.

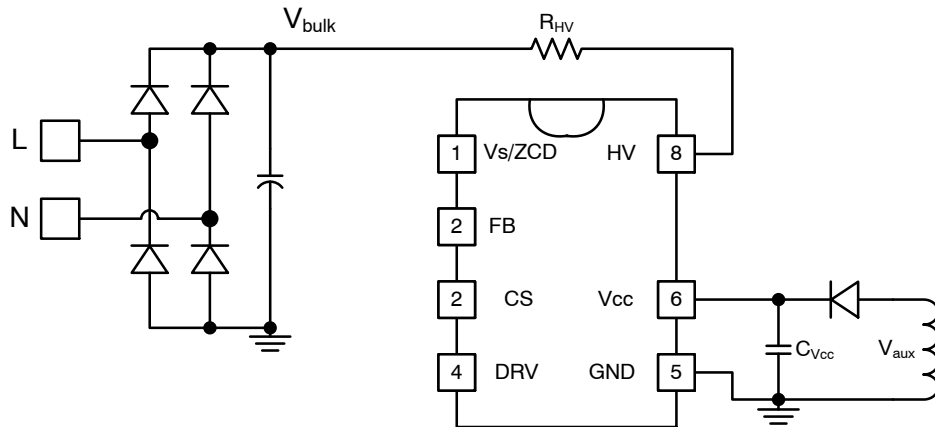

Figure 40. HV Startup Connection to the Bulk Capacitor (NCP1366)

The following calculation illustrates the time needed for releasing the latch state:

$$t_{unplug} > \frac{C_{bulk} V_{in_ac} \sqrt{2}}{I_{HV}} \quad (\text{eq. 1})$$

For the following typical application with a 10 μ F bulk capacitor and a wide mains input range, in the worst case the power supply needs to be unplug at least for 38 seconds @ 265 V ac and 12 seconds @ 85 Vac. It is important to note that the previous recommendation is no longer valid with the B version, as all the faults are set to autorecovery mode only.

Protecting the Controller Against Negative Spikes

As with any controller built upon a CMOS technology, it is the designer’s duty to avoid the presence of negative spikes on sensitive pins. Negative injection has the bad habit to forward–bias the controller substrate and can induce erratic behaviors. Sometimes, the injection can be so strong that internal parasitic SCRs are triggered and latch the controller. The *HV* pin can be the problem in certain circumstances. During the turn–off sequence, e.g. when the user unplugs the power supply, the controller is still fed by its V_{CC} capacitor and keeps activating the MOSFET ON and

OFF with a peak current limited by R_{sense} . Unfortunately, if the quality factor Q of the resonating network formed by L_p and C_{bulk} is high (e.g. the MOSFET $R_{DS(on)} + R_{sense}$ are small), conditions are met to make the circuit resonate and a negative ringing can potentially appear at the HV pin.

Simple and inexpensive cures exist to prevent the internal parasitic SCR activation. One of them consist of inserting a resistor in series with the HV pin to keep the negative current at the lowest when the bulk swings negative (Figure 40).

Another option (Figure 41) consists of connecting the HV pin directly to the line or neutral input via a high-voltage diode. This configuration offers the benefits to release a latch state immediately after unplugging the power supply from the mains outlet. There is no delay for resetting the controller as there no capacitor keeps the HV bias.

R_{HV} resistor value must be sized as follow in order to guarantee a correct behavior of the HV startup in the worst case conditions:

$$R_{HV} < \frac{V_{in,ac_min} \sqrt{2} - V_{HV(min)_max}}{I_{HV_max}} \quad (\text{eq. 2})$$

Where:

- V_{in,ac_min} is minimal input voltage, for example 85 V ac for universal input mains.
- $V_{HV(min)_max}$ is the worst case of the minimal input voltage needed for the HV startup current source (25 V-max).
- I_{HV_max} is the maximum current delivered by the HV startup current source (150 μ A-max)

With this typical example

$$R_{HV} < \frac{85 \sqrt{2} - 25}{150 \mu} = 633 \text{ k}\Omega,$$

then any value below this one will be ok.

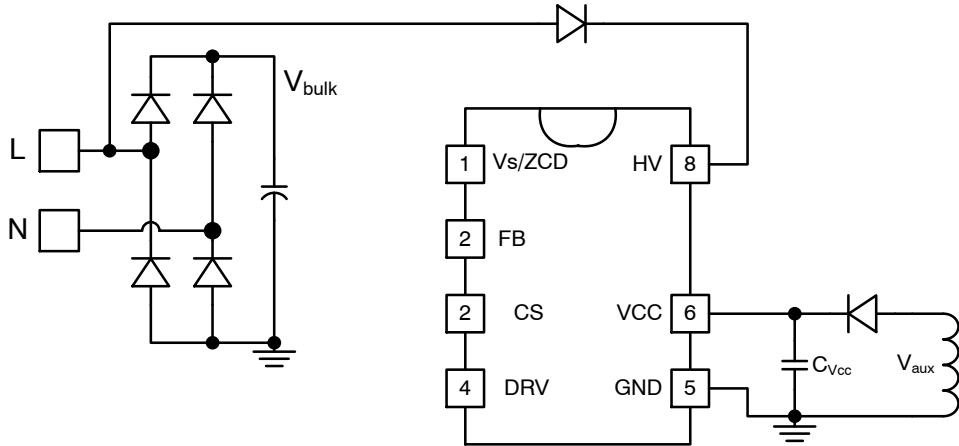

Figure 41. Recommended HV Startup Connection for Fast Release after a Latched Fault (NCP1366)

Primary Side Regulation: Constant Current Operation

Figure 42 portrays idealized primary and secondary transformer currents of a flyback converter operating in Discontinuous Conduction Mode (DCM).

Figure 42. Primary and Secondary Transformer Current Waveforms

When the primary power MOSFET is turned on, the primary current is illustrated by the green curve of Figure 42. When the power MOSFET is turned off the primary side current drops to zero and the current into the secondary winding immediately rises to its peak value equal to the primary peak current divided by the primary to secondary turns ratio. This is an ideal situation in which the leakage inductance action is neglected.

The output current delivered to the load is equal to the average value of the secondary winding current, thus we can write:

$$I_{out} = \langle i_{sec}(t) \rangle = \frac{I_{p,pk} t_{demag}}{2N_{ps} t_{sw}} \quad (\text{eq. 3})$$

Where:

- t_{sw} is the switching period
- t_{demag} is the demagnetizing time of the transformer
- N_{ps} is the secondary to primary turns ratio, where N_p and N_s are respectively the transformer primary and secondary turns:

$$N_{ps} = \frac{N_s}{N_p} \quad (\text{eq. 4})$$

- $I_{p,pk}$ is the magnetizing peak current sensed across the sense resistor on CS pin:

$$I_{p,pk} = \frac{V_{CS}}{R_{sense}} \quad (\text{eq. 5})$$

Internal constant current regulation block is building the constant current feedback information as follow:

$$V_{FB_CC} = V_{ref_CC} \frac{t_{sw}}{t_{demag}} \quad (\text{eq. 6})$$

As the controller monitors the primary peak current via the sense resistor and due to the internal current setpoint divider (K_{comp}) between the CS pin and the internal feedback information, the output current could be written as follow:

$$I_{out} = \frac{V_{ref_CC}}{8N_{ps}R_{sense}} \quad (\text{eq. 7})$$

The output current value is set by choosing the sense resistor value:

$$R_{sense} = \frac{V_{ref_CC}}{8N_{ps}I_{out}} \quad (\text{eq. 8})$$

When the power MOSFET is released at the end of the on time, because of the transformer leakage inductance and the drain lumped capacitance some voltage ringing appears on the drain node. These voltage ringings are also visible on the auxiliary winding and could cheat the controller detection circuits. To avoid false detection operations, two protecting circuits have been implemented on the V_s/ZCD pin (see Figure 43):

1. An internal switch grounds the V_s/ZCD pin during $t_{on} + t_{short_ZCD}$ in order to protect the pin from negative voltage.
2. In order to prevent any misdetection from the zero crossing block an internal switch disconnects V_s/ZCD pin until t_{blank_ZCD} time (1.5 μ s typ.) ends.

Figure 43. V_s/ZCD Pin Waveforms

Constant-Current and Constant-Voltage Overall Regulation:

As already presented in the two previous paragraphs, the controller integrates two different feedback loops: the first one deals with the constant-current regulation scheme while the second one builds the constant-voltage regulation with an opto-based voltage loop. One of the two feedback paths sets the primary peak current into the transformer. During startup phase, however, the peak current is controlled by the soft-start.

Zero Current Detection

The NCP1361/66 integrates a quasi-resonant (QR) flyback controller. The power switch turn-off of a QR converter is determined by the peak current whose value depends on the feedback loop. The switch restart event is determined by the transformer demagnetization end. The

demagnetization end is detected by monitoring the transformer auxiliary winding voltage. Turning on the power switch once the transformer is demagnetized (or reset) reduces turn-on switching losses. Once the transformer is demagnetized, the drain voltage starts ringing at a frequency determined by the transformer magnetizing inductance and the drain lumped capacitance, eventually settling at the input voltage value. A QR controller takes advantage of the drain voltage ringing and turns on the power switch at the drain voltage minimum or “valley” to reduce turn-on switching losses and electromagnetic interference (EMI).

As sketched by Figure 44, a valley is detected once the ZCD pin voltage falls below the QR flyback demagnetization threshold, $V_{ZCD(TH)}$, typically 45 mV. The controller will switch once the valley is detected or increment the valley counter depending on FB voltage.

Figure 44. Valley Lockout Detection Circuitry internal Schematic

Timeout

The *ZCD* block actually detects falling edges of the auxiliary winding voltage applied to the *ZCD* pin. At start-up or during other transient phases, the *ZCD* comparator may be unable to detect such an event. Also, in the case of extremely damped oscillations, the system may not succeed in detecting all the valleys required by valley lockout operation (VLO, see next section). In this condition, the NCP1361/66 ensures continued operation by incorporating a maximum timeout period that resets itself when a demagnetization phase is properly detected. In case the ringing signal is too weak or heavily damped, the timeout signal supersedes the *ZCD* signal for the valley counter. Figure 44 shows the timeout period generator circuit schematic. The timeout duration, t_{out} , is set to 5.5 μ s (typ.).

During startup, the output voltage is still low, leading to long demagnetization phase, difficult to detect since the auxiliary winding voltage is small as well. In this condition, the t_{out} timeout is generally shorter than the inductor demagnetization period and if used to restart a switching cycle, it can cause continuous current mode (CCM) operation for a few cycles until the voltage on the *ZCD* pin is high enough for proper valleys detection. A longer timeout period, t_{outSS} , (typically 44 μ s) is therefore set during soft-start to prevent CCM operation.

In VLO operation, the timeout occurrences are counted instead of valleys when the drain-source voltage oscillations are too damped to be detected. For instance, assume the circuit must turn on at the third valley and the *ZCD* ringing only enables the detection of:

- Valleys #1 to #2: the circuit generates a *DRV* pulse t_{out} (steady-state timeout delay) after valley #2 detection.

- Valley #1: the timeout delay must run twice so that the circuit generates a *DRV* pulse 10 μ s ($2 * t_{out}$ typ.) after valley #1 detection.

Valley LockOut (VLO) and Frequency Foldback (FF)

The operating frequency of a traditional Quasi-Resonant (QR) flyback controller is inversely proportional to the system load. In other words, a load reduction increases the operating frequency. A maximum frequency clamp can be useful to limit the operating frequency range. However, when associated with a valley-switching circuit, instabilities can arise because of the discrete frequency jumps. The controller tends to hesitate between two valleys and audible noise can be generated

To avoid this issue, the NCP1361/66 incorporates a proprietary valley lockout circuitry which prevents so-called valley jumping. Once a valley is selected, the controller stays locked in this valley until the input level or output power changes significantly. This technique extends QR operation over a wider output power range while maintaining good efficiency and naturally limiting the maximum operating frequency.

The operating valley (from 1st to 4th valley) is determined by the internal feedback level (*FB* node on Figure 4). As *FB* voltage level decreases or increases, the valley comparators toggle one after another to select the proper valley.

The decimal counter increases each time a valley is detected. The activation of an “n” valley comparator blanks the “n-1” or “n+1” valley comparator output depending if V_{FB} decreases or increases, respectively. Figure 45 shows a typical frequency characteristic obtained at low line in a 10 W charger.

Figure 45. Typical Switching Frequency versus Output Power Relationship in a 10 W Adapter

When an “n” valley is asserted by the valley selection circuitry, the controller locks in this valley until the *FB* voltage decreases to the lower threshold (“n+1” valley activates) or increases to the “n valley threshold” + 600 mV (“n-1” valley activates). The regulation loop adjusts the

peak current to deliver the necessary output power at the valley operating point. Each valley selection comparator features a 600 mV hysteresis that helps stabilize operation despite the *FB* voltage swing produced by the regulation loop.

Table 1. VALLEY FB THRESHOLD ON CONSTANT VOLTAGE REGULATION

FB Falling		FB Rising	
1 st to 2 nd valley	2.5 V	FF mode to 4 th	2.5 V
2 nd to 3 rd valley	2.3 V	4 th to 3 rd valley	2.7 V
3 rd to 4 th valley	2.1 V	3 rd to 2 nd valley	2.9 V
4 th to FF mode	1.9 V	2 nd to 1 st valley	3.1 V

Frequency Foldback (FF)

As the output current decreases (*FB* voltage decreases), the valleys are incremented from 1 to 4. In case the fourth valley is reached, the *FB* voltage further decreases below 1.9 V and the controller enters the frequency foldback mode (FF). The current setpoint being internally forced to remain above 0.12 V (setpoint corresponding to $V_{Comp} = 1.9$ V), the controller regulates the power delivery by modulating the switching frequency. When an output current increase causes *FB* to exceed the 2.5 V FF upper threshold (600-mV hysteresis), the circuit recovers *VLO* operation.

In frequency foldback mode, the system reduces the switching frequency by adding some dead-time after the 4th valley is detected. However, in order to keep the high

efficiency benefit inherent to the QR operation, the controller turns on again with the next valley after the dead time has ended. As a result, the controller will still run in valley switching mode even when the FF is enabled. This dead-time increases when the *FB* voltage decays. There is no discontinuity when the system transitions from *VLO* to FF and the frequency smoothly reduces as *FB* goes below 1.9 V.

The dead-time is selected to generate a 2 μs dead-time when V_{Comp} is decreasing and crossing V_{HVCOI} (1.9 V typ.). At this moment, it can linearly go down to the minimal frequency limit ($f_{VCO(min)} = 200, 600$ or 1200 Hz version are available). The generated dead-time is 1 μs when V_{Comp} is increasing and crossing V_{HVCOI} (2.5 V typ.).

Figure 46. Valley Lockout Threshold

Current Setpoint

As explained in this operating description, the current setpoint is affected by several functions. Figure 47 summarizes these interactions. As shown by this figure, the current setpoint is the output of the control law divided by K_{comp} (4 typ.). This current setpoint is clamped by the soft-start slope as long as the peak current requested by the *FB_CV* or *FB_CC* level are higher. The softstart clamp is

starting from the frozen peak current ($V_{CS(VCO)} = 120$ mV typ.) to V_{ILIM} (0.8 V typ.) within 4 ms (t_{ss}).

However, this internal *FB* value is also limited by the following functions:

- A minimum setpoint is forced that equals $V_{CS(VCO)}$ (0.12 V, typ.)
- In addition, a second *OC*P comparator ensures that in any case the current setpoint is limited to V_{ILIM} .

DESCRIPTION:	7-LEAD SOIC	PAGE 2 OF 2

ON Semiconductor and are trademarks of Semiconductor Components Industries, LLC dba ON Semiconductor or its subsidiaries in the United States and/or other countries. ON Semiconductor reserves the right to make changes without further notice to any products herein. ON Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does ON Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. ON Semiconductor does not convey any license under its patent rights nor the rights of others.

onsemi, **Onsemi**, and other names, marks, and brands are registered and/or common law trademarks of Semiconductor Components Industries, LLC dba "**onsemi**" or its affiliates and/or subsidiaries in the United States and/or other countries. **onsemi** owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of **onsemi**'s product/patent coverage may be accessed at www.onsemi.com/site/pdf/Patent-Marking.pdf. **onsemi** reserves the right to make changes at any time to any products or information herein, without notice. The information herein is provided "as-is" and **onsemi** makes no warranty, representation or guarantee regarding the accuracy of the information, product features, availability, functionality, or suitability of its products for any particular purpose, nor does **onsemi** assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. Buyer is responsible for its products and applications using **onsemi** products, including compliance with all laws, regulations and safety requirements or standards, regardless of any support or applications information provided by **onsemi**. "Typical" parameters which may be provided in **onsemi** data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. **onsemi** does not convey any license under any of its intellectual property rights nor the rights of others. **onsemi** products are not designed, intended, or authorized for use as a critical component in life support systems or any FDA Class 3 medical devices or medical devices with a same or similar classification in a foreign jurisdiction or any devices intended for implantation in the human body. Should Buyer purchase or use **onsemi** products for any such unintended or unauthorized application, Buyer shall indemnify and hold **onsemi** and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that **onsemi** was negligent regarding the design or manufacture of the part. **onsemi** is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
